SCRIP is a certificate (usually about the size and appearance of a bank-note) of a person's share or shares in a joint-stock undertaking. It is issued on the party signing a contract of copartnery, and is retained by him until an act of the legislature, or some other formality, establishes the company, and authorises the opening of regular books for entering the names of shareholders and the transfer of stock. In many instances, scrip is unauthorisedly sold, and made an object of speculation; the party to whom it was assigned, however, remains bound by the contract which he has subscribed, until relieved of his obligations by transfer in the books of the company.

SCRO'FULA, or SCROPHULA, was, until the last quarter of a century, regarded as consisting essentially of indolent glandular tumours, occurring frequently in the neck, suppurating slowly and imperfectly, and healing with difficulty. Recent pathologists, however, have given a more extended meaning to the word *scrofula*. According to them, it signifies a certain disease or defect of the constitution, in which there is a tendency to the production and deposition of a substance called *tubercle* in various tissues and organs; and tubercle must thus be regarded as the essential element of scrofula. It does not follow, however, that a deposit of tubercle should actually occur in every case of scrofula. The *tendency* is present, and the absence or presence of the deposit depends upon the extent of the affection, and is determined by various causes.

Mr Paget, one of the most eminent of our living pathologists, very clearly sums up what is generally understood by scrofula in the following paragraph: 'It is a state of constitution distinguished in some measure by peculiarities of appearance even during health, but much more by peculiar liability to certain diseases, including pulmonary phthisis. The chief of these "scrofulous" diseases are various swellings of the lymphatic glands, arising from causes which would be inadequate to produce them in ordinary healthy persons. The swellings are due sometimes to mere enlargement, as from an increase of natural structure, sometimes to chronic inflammation, sometimes to an acute inflammation or abscess, sometimes to tuberculous disease of the glands. But besides these, it is usual to reckon as "scrofulous" affections certain chronic inflammations of the joints; slowly progressive "carious" ulcerations of bones; chronic and frequent ulcers on the Cornea, Ophthalmia [q. v.], attended with extreme intolerance of light, but with little, if any, of the ordinary consequences of inflammation; frequent chronic abscesses; pustules, or other cutaneous eruptions, frequently appearing upon slight affection of the health or local irritation; habitual swelling and catarrh of the mucous membrane of the nose; habitual swelling of the upper lip.' It is obvious that although the above-named forms of disease are often more or less coincident, they have nothing sufficiently in common to justify the general appellation of *scrofulous*. They are certainly not all tuberculous diseases, and hence Mr Paget doubts whether the proposal to make *scrofulous* and *tuberculous* commensurate terms is practical, since the former, as generally employed, has a much wider significance than the latter.

The word is derived from the Lat. *scrofa*, a sow, it being supposed that this animal was especially liable to tumours such as occur in this disease. The Greek and Arabic names for the disease are similarly derived from the words signifying 'swine' in these languages. While *scrofula* was the popular, *struma* (supposed to be derived from *struo*, I heap up) used by Celsus, Pliny, and other Latin writers, was the classical name for the disease. The vulgar English name, *The King's Evil*, is derived from the long-cherished belief that scrofulous tumours and abscesses could be cured by the royal touch. Multitudes of patients were submitted to this treatment, and, as the old historians assert, with perfect success, from the time of Edward the Confessor to the reign of Queen Anne. The writer of the article 'Scrofula' in *The English Cyclopædia*, mentions the curious historical facts that 'the old Jacobites considered that this power did not descend to Mary, William, or Anne, as they did not possess a full hereditary title, or, in other words, did not reign by divine right. The kings of the house of Brunswick have, we believe, never put this power to the proof; and the office for the ceremony which appears in our Liturgy as late as 1719 has been silently omitted. The exiled princes of the house of Stuart were supposed to have inherited this virtue. Carte, in the well-known note to the first volume of his *History of England*, mentions the case of one Christopher Lowel, who, in 1716, went to Avignon, where the court was then held, and received a temporary cure; and when Prince Charles Edward was at Holyroodhouse in October 1745, he, although only claiming to be Prince of Wales and regent, touched a female child for the king's evil, who in 21 days is said to have been perfectly cured.' The practice was introduced by Henry VII. of presenting the patient with a small coin (gold or silver). The accompanying is an engraving of the identical touch-piece presented to Dr Johnson (Lent 1712—when he was only thirty months old), who was one of the persons touched by Queen Anne.—The French kings also touched for the 'Evil,' the practice being

traced back to Clovis, 481 A. D. On Easter Sunday, 1686, Louis XIV. is said to have touched 1600 persons, using the words: *Le roy te touche, Dieu te guérisse* (the king touches thee, may God cure thee). See Chambers's *Book of Days*, i. 82. The

Touch-piece (time of Queen Anne).

literature of this curious subject is somewhat extensive. The reader who wishes to pursue the inquiry further is referred to Tooker's *Charisma, sive Donum Sanctionis*, &c., 1597; Browne's *Charisma Basilicon, or the Royal Gift of Healing Strumæ*, &c., 1684; and Beckett's *Free and Impartial Inquiry into the Antiquity and Efficacy of Touching for the King's Evil*, 1722. The subject is also examined by Bishop Douglas in his *Criterion, or Miracles Examined*, 1754; by Colquhoun, in his *Isis Revelata*, 1836 (who attributes the cure to animal magnetism); and by Howitt in his *History of the Supernatural in all Ages and Nations*, 1863.

Scrofula is a disease of early life, and when it does not exhibit any of its manifestations before the period of maturity it seldom shews itself afterwards.

In all systematic descriptions of this disease, two varieties of the scrofulous habit or diathesis are given, viz., the *sanguine* or *serous*, and the *phlegmatic* or *melancholic*. In the *sanguine*, there is a general want of muscular development, the limbs being soft and flabby; the skin is fair and thin; the features are delicate, the rosy hue of the cheeks contrasting strongly with the surrounding paleness; the eyes are gray or blue, and the eyelashes long and silken; the hair fine and light coloured or reddish; and the ends of the fingers broad and expanded, with convex nails bent over them; the intellect is lively and precocious, and there is often considerable beauty. In the *phlegmatic* variety the skin is pale or ruddy, dark, and often harsh; the general appearance dull and heavy; the hair dark and coarse; and the mind usually slow and torpid.

Children in whom the scrofulous constitution is strongly marked often present that narrow and projecting form of the chest to which the term 'pigeon-breasted' is commonly given; moreover, the abdomen is enlarged, the limbs wasted, and the circulation languid, in consequence of which they are especially liable to chilblains. The digestive organs are so commonly affected—as is evidenced by irregular action of the bowels, fetid breath and evacuations, furred tongue, capricious appetite, &c.—that, in the opinion of the late Dr Todd, 'strumous dyspepsia presents a more characteristic feature of this habit of body than any physiognomical portrait that has been drawn of it.' In the great majority of cases, the scrofulous disposition is hereditary; indeed, there is no disease which is nearly so often transmitted from parent to offspring as scrofula. There is, however, scarcely any doubt that it may be acquired under the action of various unfavourable exciting causes, which may be ranked together 'as causes of debility.' Amongst them may be especially noticed (1.) Insufficient and improper food; (2.) Impure air; (3.) Insufficient exposure to direct sunlight; (4.) Exposure to wet and cold, and to sudden changes of temperature, especially if the clothing be insufficient; (5.) Excessive and continued fatigue, whether bodily or mental; and (6.) Intense and prolonged anxiety or mental depression.

We shall first lay down the general principles of treatment to be adopted with the view of improving the health in the case of a person presenting either merely the general indications of a scrofulous habit of body, or some of its local manifestations, and we shall then conclude with a brief notice of a few of those particular forms of the disease which most frequently come under the attention of the medical practitioner.

The diet should be nutritious and sufficiently abundant, and animal food should be given at least twice daily. Dishes containing eggs and milk may usually be taken with advantage. If the patient is not very young, a little bitter ale taken at an early dinner will often promote digestion; if, however, it causes flushing or much sleepiness, it must be discontinued. A mother with scrofula should always provide a healthy wet-nurse for her child, as suckling in such a case is injurious both to parent and offspring. Flannel should always (both in summer and winter) be worn next the skin during the day, and the clothing must always be sufficient to keep the extremities warm. Constant residence in pure and dry air should be enforced as far as possible. Unfortunately, the climate of Great Britain is by no means favourable to those possessing the scrofulous habit, and it is often very difficult for the physician to decide as to the choice of the most suitable residence. On this subject, Mr Savory, in his essay on 'Scrofula' in Holmes's *System of Surgery*, vol. i., 1860, remarks that 'it is surely a mistake to suppose that a warm climate is the best adapted to all cases of scrofula. It is doubtless so in the great majority in which the disease [in the form of pulmonary consumption] is far advanced; but in many cases at an earlier stage, its further development is more satisfactorily arrested and the general health improved by a more bracing air. Children with tuberculous glands, but whose general health appears otherwise tolerably good, would perhaps profit less by transportation to Madeira or Egypt than by residence in the south-west coast of England, where the atmospheric changes are less frequent and sudden than in other parts of the kingdom, and the winter is comparatively mild. Delicacy of constitution is sometimes increased, and mischief encouraged, by dread of exposure.' Free exercise of the muscles and lungs in the open air should be insisted on in fine weather, and if this cannot be taken, the best substitute is friction over the surface of the body with the flesh-brush. Patients who can bear cold sea-bathing during the summer and autumn months will derive great advantage from it; but if a short immersion is not rapidly followed by a genial glow after drying the skin, such bathing is injurious, in which case warm salt-baths will be found useful. Too much stress cannot be laid upon the fact that in the case of children the mind should be cheerfully occupied, but not overtasked. The medicines most esteemed in the treatment of scrofula are iodine and its compounds, the salts of iron, bark, sarsaparilla, the alkalies and mineral acids, and, above all, cod-liver oil. As the choice of the individual remedy must be left to the physician, we will merely remark that iodine and iron may often be advantageously prescribed together either in the form of the syrup of the iodide of iron, or of a well-known French preparation known as Blancard's Iodide of Iron Pills; and that

to derive full benefit from cod-liver oil, it must be taken for a long time. As Mr Savory remarks, the oil should be regarded as an article of diet rather than a medicine. A tablespoonful may be considered as a full dose for an adult; but this quantity should be gradually arrived at, the dose commencing with a teaspoonful. It is most easily taken when floating on a mixture of orange wine, or some other pleasant bitter fluid, with water. The lightest and clearest oil is probably the best, and in cold weather it should be slightly warmed before it is taken, for it is thus rendered more liquid and more easily swallowed. If what are commonly known as 'bilious symptoms' supervene, the use of the oil should be suspended for a couple of days, and a few gentle aperients should be prescribed.

Excluding pulmonary consumption, in which the leading pathological feature is the deposit of scrofulous matter or tubercle in the lungs, one of the forms of scrofula which most frequently presents itself is in the *lymphatic glands*, especially of the neck. The gland or glands may first become enlarged, either from an attack of acute inflammation, or from an indolent and painless deposit of tubercle. They may remain in this state either stationary or slowly enlarging for years, till from some accidental local irritation, or from some constitutional disturbance, they inflame and suppurate. After the discharge of the matter, the ulcerated skin usually heals with an ugly puckered cicatrix, which generally remains as a disfiguring mark through life. The local treatment consists in attempting to disperse the tumour, if it is hard and painless, by painting it with tincture of iodine, or by the application of iodine ointment. If it is soft, and likely to suppurate, the process may be facilitated by the application of warm water dressing or emollient poultices. When there is undoubted fluctuation, indicating the presence of pus or matter, it is usually regarded as the best practice to open the abscess with a narrow-bladed bistoury; but some surgeons still prefer allowing the matter to make its own way to the surface. The necessary internal treatment is that which has been already described. The *skin*, especially behind the ears, about the mouth, nostrils, and eyelids, and on the scalp, is liable to pustular diseases of a scrofulous origin. The free use of soap and water, followed by the application of black wash or zinc ointment, and proper constitutional treatment, will generally effect a cure, except in the horrible form of scrofulous ulceration of the skin of the face known as *Lupus* (q. v.). Amongst other well-known and very serious scrofulous affections must be mentioned *Acute Hydrocephalus* and *Mesenteric Disease*, to which special articles are devoted. There is a peculiar and very intractable form of ulceration known as the *scrofulous ulcer*, which will be noticed in the article on Ulcers. The physical, chemical, and microscopical characters of the peculiar morbid deposit, to which reference has frequently been made in this article, will be found under the head of Tubercle and Tuberculosis.

Scrofulous or Tuberculous Diseases are common amongst cattle, sheep, and pigs. In early life the tubercle is laid down in the mesenteric gland, and occasionally about the joints. Along the exposed eastern coasts of Britain, scrofulous swellings are also met with about the head and neck; in some of the great grazing districts, the mucous membrane of the bowels is affected, constituting dysentery; but, as in man, the lungs are the most common site of tubercle, which here gives rise to pulmonary consumption. Scrofula in all its forms is hereditary, hence animals with any such taint should be rejected as breeding stock. It is induced and fostered by 'breeding in and in.' It may be developed, and is always aggravated, by debilitating influences, such as bad food, or exposure to wet or cold. Prevention is insured by breeding only from healthy vigorous parents, and allowing the stock at all times adequate food and shelter.

SCROLL, an ornament of very common use in all styles of architecture. It consists of a band arranged in convolutions, like the end of a piece of paper rolled up. The Greeks used it in their Ionic and Corinthian Styles (q. v.); the Romans in their Composite; and in medieval architecture, and all styles which closely copy nature, it is of constant occurrence as in nature itself.

SCROPHULARIA'CEÆ, or SCROPHULARI'NEÆ, a natural order of exogenous plants, consisting chiefly of herbaceous and half-shrubby plants. The calyx is inferior, persistent, divided into five (sometimes four) unequal divisions. The corolla is monopetalous, more or less irregular, often two-lipped, exhibiting great variety of form; in the bud it has five (sometimes four) segments. The stamens are usually four, two long and two short, sometimes two, rarely five. The ovary is 2-celled, with many ovules; the style simple, the stigma generally 2-lobed. The lobes of the stigma sometimes display much irritability. The fruit is a capsule, or rarely a berry.—This order is a very large one, containing almost 2000 known species, which are distributed over the whole world, both in cold and warm climates. Acridity and bitterness are prevalent characteristics, and many species are poisonous. Some are root parasites. Some are admired and cultivated for their flowers; some are used medicinally. *Digitalis* or Foxglove, *Calceolaria*, *Mimulus*, Mullein, *Antirrhinum* or Snapdragon, *Gratiola*, *Scrophularia* or Figwort, *Veronica* or Speedwell, and *Euphrasia* or Eyebright, are familiar examples. Very different from these humble herbaceous plants is *Paulownia imperialis*, a Japanese tree, 30 to 40 feet high, with trunk two or three feet in diameter, and flowers in panicles, about as large as those of the Common Foxglove.

SCRUPLE (Lat. *scripulum*, *scriplum*, or *scrupulum*) was the lowest denomination of weight among the Romans, and with them denoted the 24th part of an ounce (*uncia*), or the 288th of a pound (*libra*). As a measure of surface it was also the 24th part of the *uncia*, and the 288th of an acre (*jugerum*); seeming, in fact, to be the 24th of the 12th part of any unit. In later Roman times it became the name of the 60th part of an hour, and corresponded to our 'minute.' The 'minute' being the *scrupulum*, the 60th part of a minute was called a *scrupulum secundum* (whence the derivation of our word 'second'), the 60th part of this a *scrupulum tertium*, and so on. Lexicographers define 'scrupulum' to be a small pebble, such as would be likely to find its way between the sandal and the foot, whence the use of the term to signify a small difficulty or objection.—The term at the present time is a denomination in that modification of Troy weight which is used by apothecaries; it contains 20 Troy grains, is the third part of a drachm, the 24th of an ounce, and the 288th of a Troy pound.

SCUDERY, Madeleine de, a once notable French novelist, was born at Havre in 1607. Left an orphan at the age of six, she, along with a brother named Georges, was carefully educated by one of her uncles. While still young, she left Normandy for Paris, was admitted to the Hôtel Rambouillet (see Rambouillet), and soon became one of the oracles of the brilliant society that assembled there. It was in this famous but shewy circle that Mademoiselle S. gathered that immense fund of watery sentimentalism, platonic

gallantries, 'polished' conversation, dull ceremonial incidents, affectations of moral purism, &c., which make up the tedious contents of her romances—*romans de longue haleine* (long-winded romances), as they have been felicitously nicknamed. Their popularity for a brief period was painfully wide. Everybody with the slightest pretensions to 'taste,' except the Port-royalists, Bossuet, and a few critics of the stricter sort, professed a boundless admiration for them. The bishops in general—as Camus, Mascaron, Huet, Godeau, Fléchier, Massillon—were in raptures, and studied the stately trash with an ardour that considerably diminishes our respect for their understanding. When the troubles of the Fronde had broken up the gatherings at the Hôtel Rambouillet, Mademoiselle S. organised a literary circle of her own, which met every Saturday at her house in the Rue de Beauce. These 'Saturdays' began very well; but gradually they degenerated, and became ridiculous—pedantic and blue-stockingish they had been from the very first. Nothing further in Mademoiselle S.'s life calls for notice. She died at Paris, 2d June 1701, at the advanced age of 94, honoured and respected to the last; and it is but fair to admit that she seems to have been worthy of the regard in which she was held, being herself a perfect pattern of those watery virtues and superfine excellences of demeanour that she loved to depict. Her principal works (never again to be read in this world) are: *Ibrahim, ou l'Illustre Bassa* (Par. 4 vols. 1641); *Artamène, ou le Grand Cyrus* (Par. 10 vols. 1649—1653); *Clélie, Histoire Romaine* (Par. 10 vols. 1656); *Almahide, ou l'Esclave Reine* (Par. 8 vols. 1660); *Les Femmes illustres, ou les Harangues Héroïques* (Par. 1665); 10 vols. of *Conversations Nouvelles, Conversations Morales*, and *Entretiens de Morale* (1680—1692); besides *Lettres*, and *Poésies légères*, &c.—See Victor Cousin's *La Société Française au Dixseptième Siècle.*

SCU'DO (Ital. shield), an Italian silver coin, corresponding to the Spanish *piastre* (q. v.), the American dollar (q. v.), and the English crown (q. v.). It was so called from its bearing the heraldic shield of the prince by whose authority it was struck, and differed in value in the different states of Italy. In Rome, where it is called the *scudo Romano* or *scudo nuovo*, it is equal to 4*s.* 3*d.* sterling; and is subdivided into 10 *paoli* or 100 *bajocchi.* The Venetian scudo, or *scudo della croce*, was of higher value than the Roman one; while, on the other hand, the old scudi of Bologna, Genoa, and Modena are inferior to it in value. Scudi are now gradually disappearing from the provinces of the Kingdom of Italy before the new decimal coinage, but the name is sometimes given to the piece of 5 lire, equivalent to a 5 franc piece in the French coinage. Scudi of gold are also struck in Rome, the *scudo d'oro* being equivalent to 10 *scudi di argento.* See PIASTRE.

SCULL, SCULLING. A scull differs from an oar in size only. It is shorter, and less heavy. A man can only manage one oar; but he can pull with a pair of sculls, the ends of which lap over very little, or else do not meet within the boat.

Sculling has two senses, a river sense and a sea sense. In its freshwater acceptation, sculling is the act of propelling a boat by means of sculls in pairs. Among seafaring men, however, to scull is to drive a boat onward with one oar, worked like a screw over the stern.

SCU'LPTURE, the process of graving or cutting hard materials; from the Lat. *sculpo*, in Gr. *glypho.* Its common application is to artistic carving or cutting. Sculpture is the art of expressing ideas or images in solid materials. In this sense processes which do not, strictly speaking, involve the cutting of hard substances are included in the term. Sculpture, as an art, includes the moulding of soft materials as well. Clay, and even wax, has been in all ages of the art employed, sometimes for the purpose of sketches or models for reproduction in marble or metal, sometimes as the material of the finished work. The art of sculpture is as old as any that has been handed down to us. The Scriptures allude to the working of brass and other metals in the beginning of human society, and we read of the images of Laban carried off by his daughter. The great nations of antiquity all practised it, though only Nineveh and Egypt have left us anything like a fair representation of the state of the art in those early times. From the nature of this art its productions have proved more durable than those of painting, and have come down to us in more numerous instances even than works of architecture. While the latter have been destroyed, and their materials used up, works of sculpture, being smaller, have remained buried, and from time to time have been reproduced for the instruction and enjoyment of modern nations.

As an art, or means of recording facts and representing ideas, sculpture has many disadvantages as compared with painting, neither colour nor picturesque backgrounds being properly admissible in sculpture. To this rule, however, we shall find exceptions in the works of Ghiberti in the 15th century.

Sculptures are distinguished by different terms, according to the nature and completeness of the work. Groups or figures completely represented are said to be 'in the round.' Those only partially detached from the mass or background are said to be 'in relief.' This, again, is called 'high' or 'low relief,' according as the figure stands fully or slightly above the mass behind it. The ancient Egyptians employed another kind of relief, their figures being sunk below the surface, and only the prominent portions remaining level with it. In this case the background or unoccupied space is not cut away, but the figures are worked downwards into it. Another process is called 'intaglio,' the whole figure being regularly designed and moulded, but 'cut into' the material and inverted. This is usually applied to the making of gems and seals. Another sculptural process is that used in the treatment of metals. As metals are both harder than stone and more valuable, it is not possible to cut or grave works out of masses of metal as is done in stone or gems. The metal is fused by heat, and the form is given it while in that state. This is done by first forming or moulding the design in clay or other soft material. Round the model thus formed, a mould is formed of sand, which is prepared and pressed round it in a wet state till it takes the complete form of the model, which is then removed, and the liquefied metal poured in. It takes the exact shape of the model by this means. These are said to be 'cast,' because of the casting of the liquid metal into the mould. Other processes, however, have, in the finer works, to be applied. The metal retains the rough surface of the sand in which it has chilled. It is therefore worked over with a graving tool, to give it a final surface, and express every delicacy of form intended by the artist. In some cases this 'engraving' is in the form of ornamental design, such as dress, &c. Sometimes the whole design is engraved without any previous casting. In this case the metal has had its form given by 'hammering' or 'beating.' The metal, hot in the case of iron or bronze, or cold in the case of silver and gold, softer metals, is beaten on the anvil into its form. A coarser and deeper method of engraving is called

'chasing,' where deeper sinkings and bolder prominence are given to the different parts of the design.

Of moulding we have already spoken. We may now remark on the materials in use for these various purposes. In sculpturing, or cutting designs or figures, we generally find marbles have been employed; the most famous having been the 'Parian,' from the Isle of Paros, and the Pentelic, from the mountain of that name in Attica. Besides these, the ancients used numerous marbles—white, and latterly coloured: the late classical sculptors sometimes employing both white and black, or coloured, in lumps on the same work, the coloured marble being used for the dress or hair as it might be. The Egyptians, besides the use of these materials, and various kinds of fine and coarse-grained stone, employed porphyry, purple and black, an exceedingly hard and difficult material to handle. The modern sculptors have used the white marble of Carrara in Italy, an excellent material, but liable to veins and discolorations, which are unfavourable to the art. 'Terra Cotta,' or burnt clay, was extensively in use both in ancient and modern times; the clay being moulded to the utmost delicacy while soft, and then baked to a red colour. Singularly fine reliefs remain to us from the Etruscans and Greeks, as well as from Egypt and elsewhere, as may be seen in the British Museum. It has also been extensively used in modern times. The Egyptians modelled little figures in porcelain clay, and coloured and enamelled them after the fashion of porcelain, and vast numbers of such are in most of our museums. The word 'toreutic,' from the Greek word *toreuo*, to pierce or bore, is usually applied to sculpture in metal. For this the metal most appropriate, and most generally used both in ancient and modern times, is 'bronze,' a mixture of copper and tin. It is also known as 'brass.' Other metals, in small quantities, were also introduced, and various kinds of bronze have resulted from this variety, as well as from the proportions of the two principal metals, the method of fusion, &c. Egina, Delos, and Corinth made different kinds of bronze, each of excellent quality. Besides this favourite metal, gold, silver, copper, and even lead, and mixtures of lead and tin, 'pewter,' have been used for artistic sculpture. In the celebrated period of Greek sculpture, gold and ivory were used together. These statues, two of which were made by Phidias, were called 'chryselephantine'—that is, of gold and ivory.

The ordinary modes of proceeding in sculpture have been very various; whether the more celebrated sculptors of ancient times cut out their designs at once without the previous rehearsal of a model, we do not know. It is, however, very probable. The Egyptian bas-reliefs may still be seen in some of their tombs, lined out, and corrected afterwards by a master's hand previous to execution. Michael Angelo, the most powerful of modern sculptors, is known to have worked many of his statues, without the use of any model, out of the blocks. Florence, and the Louvre (Paris), contain marble sketches or unfinished figures thus roughed out. The length and size of the chisel-marks shew how boldly this great master went to work to within $\frac{1}{8}$th of an inch of his final surface. As, however, there can be no putting on of any of the substance of stone once reduced by inadvertence, the artist commonly makes his sketch or design, in small, in clay. This is subsequently enlarged, and then studied from 'the life;' that is, men, horses, draperies, &c., the most suitable to the artist's present purpose are selected, and with these before him, he corrects his design and perfects it while the material is soft. A mould is then taken, as in the case already described, and with a plaster instead of a metal cast before him, the artist proceeds to work on his marble. The cast being placed on one block, and the marble on one precisely similar, workmen proceed to place a needle on a measuring-rod, the rod resting against the block till it touches a point of the cast. The needle is then applied to the block on which the marble stands, and this is bored into till the needle touches it as it did the cast. In this way the distance of the various surfaces of the future figure from the outside of the unshaped marble are ascertained, and the workmen rough out the figure down to those measurements. The sculptor then gives the final and delicate touches that finish it, himself. Finally, it is brought smooth with pumice-stone or sand. Michael Angelo and some of the ancients actually polished their statues. This, however, is generally objected to, as the sharp points of reflected light injure the general effect of the form.

We must notice one other question relative to sculpture before proceeding to a short review of the art historically, that is colour. The ancients—that is, Egyptians, Ninevites, and others—did colour their statues, intending, probably, to do so up to 'life'—that is, to a direct imitation. The Greeks, too, employed colour on their statues, certainly on their architecture. To what extent they coloured their statues, it is not very easy to determine. Partly, indeed, time has so altered, and partly so obliterated the colouring material, that we can only form an approximate judgment. It seems probable that the colouring was conventional, that is, that colour was used to add to the splendour and distant effect of the work, rather than to attempt any positive imitation of real life. A head in the Elgin Room of the British Museum has been coloured, the hair full red. The eyes are completely cut out, so as to shew dark and shadowy hollows, even with the face coloured. Gilding, too, was used for the hair. Colour was extensively used in the middle ages. Many, if not most, interior sculptures were coloured during that period. Quite in our own days Mr Gibson has coloured female statues. It is open to doubt whether they can be called successful as far as the colour goes. Other means, however, were used to give colour in late classic times, as may be seen in the Vatican, where a bust retains both enamelled eyes and black eyelashes inserted into the marble. To the mixture of marbles to obtain the effect of colour we have already alluded.

Speaking of sculpture generally, we may say that a great deal has come down to us. Of the best work known, that of Phidias, our readers will see notices under the head of the ELGIN MARBLES. The majority of portable works are statues. Of these, some calculations reckon as many as 60,000 of one kind and another.

Fragments of these have various terms applied to them. 'Busts' are heads, or heads and chests; a 'torso' is a figure without head or limbs. These are perhaps fragments. Horace, however, is supposed to allude to a recognised form of such pieces of sculpture in the words 'mediam minervam.' Statues are called 'terminal' when they consist of a head only made out, the body being represented by a square post. These were set up as boundary marks, to invoke favourite deities for the owner's prosperity, and hence the name 'terminal.'

We now proceed to a very summary survey of the history of sculpture. We have said that ancient nations, both of profane and sacred history, were well used to sculpture. Of these, the Egyptian and the Ninevite are best known. The Egyptian sculpture goes back as far as 1700, or even, in the case of the Pyramids, to 2000 years before Christ (Gardner Wilkinson, *Ancient Egyptians*). Both sculptured the human form, the Egyptians with

most knowledge and refinement; both were restricted by religious traditions from arriving at a full representation of the human form; both used mixed forms of man-headed bulls, or man-headed and ram-headed lions. Usually these were colossal. The Egyptians, besides this, covered the walls of their sepulchres and temples with spirited and amply detailed historical representations.

The next great nation of whose productions we can judge was the Etruscan. They were of Greek origin. There is a great oriental influence or character in their work. It is also to some extent conventional, but often full of sublimity, and the figure quite correct in outline. This also is illustrated by their pottery, covered with figure designs, of which great abundance has been excavated in various parts of Italy. All these schools, including the Etruscan, are stiff and dry in execution—that is, wanting in the ease, fulness, and movement of the human form. They are called 'archaic,' meaning by that term unformed and undeveloped, belonging to an age uninstructed in technical knowledge.

Beginning with the early Egyptian times, this first period, called Archaic, may be concluded with those of the Etruscans, and brings us down to about 600 B.C. From this time a rapid growth in the art took place; schools were formed in the great cities of Greece, Sicyon, Egina, and Corinth; and we read of Callon, Onatas, Glaucias, and other names, culminating in Ageladas of Argos. These men sculptured on a colossal scale, and we have already alluded to the bronze for which the Greek cities had long been famous. These schools produced the famous works known as the Egina Marbles, found in 1812, as well as those of Selinus, in Sicily. Casts of the former may be seen in the British Museum. The originals are at Munich.

The great period of sculpture began about 484, when Phidias was born. Ageladas was his master, as also of Polycletus and Myron, of whose works copies are now in the Vatican and elsewhere, made by Greek artists in the times of the Roman empire.

Of the great work of Phidias we will not here treat, as it is described elsewhere. Pericles did much to encourage the arts both of sculpture and painting.

For a century and a half, or for two, sculpture continued very slowly to decline. This great school ended in Praxiteles, a sculptor of consummate powers. He carried the representation of the human form further than Phidias and his scholars, and draperies in his hands lost their severer character, and clung to the rounded limbs, which they no longer concealed. His work may be seen in the casts of the Nike Apteros, or sculptures of the temple of unwinged Victory, in the British and other museums. He is said to have been the first to represent the female form quite nude, and to have contributed by such sculptures to the enervation and gradual sensualising of the art.

During the 5th and 4th centuries B. C., we have Agoracritos of Paros; Alcamenes of Athens; Scopas, the author of the famous Niobe group now at Florence; Lysippus of Sicyon, the favourite of Alexander; Chares, the author of the famous Colossus of Rhodes; Agasias, who sculptured the 'Fighting Gladiator;' Glycon of the Farnese Hercules; and many others.

The Roman conquest of Corinth under Mummius in the 2d c., and afterwards of Athens, brought this old art to an end. Thenceforth, Greek artists were found all over the Roman empire, and the famous works of these former sculptors were reproduced by them for their new masters. The Roman sculpture, indeed, is included in this phase of Greek art—the last remarkable work that we shall notice of classic times being the famous column of Trajan, in the early part of the 2d c. A.D. This is, in fact, a tower over 100 feet high, of white marble, entirely covered with bas-reliefs representing the Dacian wars of Trajan. We here see the expiring effort of classic art. Skilful and correct as the design is, it is, as a whole, graceless, stiff, and without beauty, compared with the old work.

Constantine, in the 4th c. of our era, carried off to Byzantium, his new seat of government, all the sculpture he could remove.

The art revived in Italy. As early as the 10th c., sculpture exhibited both design and grandeur, though wholly different from that of older times. Absolute freedom from old conventionalities, vigour, dignity, and childlike freshness of mind, distinguish modern sculpture down to the 15th century. The most noted names we will mention here are those of Niccolo of Pisa, in the 13th c., who executed the bas-reliefs at Orvieto; after him, his son Giovanni. Andrea Pisano made one of the bronze gates of the baptistery of Florence. Ghiberti, the author of the more famous doors of the same baptistery, is next to be named; then Donato di Betto Bardi, or Donatello. Some of his works are in the church of Or san Michele, which the famous Orcagna, sculptor, painter, and architect, had built and decorated.

We begin the next period with Verocchio, in the 15th c., and the more famous Michael Angelo in the 16th. A host of great names followed: Cellini, Torregiano (who made the monument of Henry VII. at Westminster), Della Porta, Giovanni di Bologna, and Luca della Robbia, who also worked in enamelled terra-cotta on a large scale. These are Italian names. We may add Jean Goujon and Germain Pilon in France. In our own country, splendid medieval works are to be seen in the noble sculptures of Wells Cathedral, and of that of Lincoln, coeval with those of the Pisani. Cibber, who sculptured in England, was a Dane. Thorwaldsen, a native of Iceland; Canova, an Italian; and, lastly, Flaxman, bring us down to our own days. Of the latter, the finest work is perhaps the Wellington Shield, after the Homeric description of that of Achilles. See the works of Winckelmann, and Kugler, and Westmacott's *Handbook of Sculpture*.

SCULPTURED STONES. In Norway, Denmark, the Isle of Man, Wales, Ireland, and Scotland, a class of monuments is to be found decorated with rude sculpture, and belonging to the early periods of Christianity—sometimes, indeed, shewing the symbols of paganism in conjunction with those of Christianity. By far the most remarkable stones of this description are those found in Scotland, which, with some points common to them with the rest, possess the distinguishing feature of a class of characters or symbols of mysterious origin, whose meaning yet remains an enigma to antiquaries, and which yet recur with such constancy in different combinations, that it is impossible to suppose their form to be the work of chance. Along with these symbols the figure of the cross is often found on one side. Neither in Ireland, in Wales, nor anywhere else, are the symbols in question to be met with. These monuments all occur within a circumscribed part of Scotland. None are to be found either within the ancient Dalriada, or south of the Forth; their limit seems to be the eastern lowlands from Dunrobin to Largo Law, or the part of Scotland inhabited by the Pictish race. From 150 to 200 of them are known to exist. The most interesting as well as the most numerous specimens are in Strathmore, at Glammis, Meigle, and Aberlemno. Among the various theories which have been formed regarding these stones,

one is, that they were boundary stones, the cross denoting the possession of the church, and the mysterious figures having reference to the lay lord; but those antiquaries who have devoted most attention to the subject, including Mr John Stuart, have come to the conclusion that they are sepulchral. The practice of erecting stones to commemorate deceased persons of note, existed in Scotland in pagan times, and, like other pagan practices, it was turned to Christian purposes by the earliest preachers of Christianity. Most of these monuments are of unhewn stone, and more or less oblong in shape; a very few have the form of a cross. A sculptured cross is met with on about half of them, the class without crosses belonging chiefly to Aberdeenshire, though a few of them are to be found in the country north of Spey. Among the symbols to which we have alluded, one of the most frequent, which has been likened to the letter Z, consists of a diagonal line, from whose extremities are drawn two parallel lines terminating in some sort of ornament. This Z symbol is often

Fig. 1.—Dunnichen Stone.

traversed with what has been called the *spectacle ornament*, consisting of two circles decorated within with foliated lines, and united by two reversed curves, or occasionally intertwined with a serpent. Another prevalent symbol is a crescent, sometimes appearing by itself, more frequently with two lines drawn through it, diverging diagonally from a point below its centre, and terminating in a floral or other ornament. A mirror and comb, a horse-shoe arch, a fish, and a figure like a fibula, are also all occasionally met with. Similar devices to the above have been found engraved on certain silver ornaments discovered on Norrie's Law, including a figure occurring on the Dunnichen Stone, which had been taken by ingenious theorists for the high cap of the Egyptian Osiris, surmounted by a lotus, but which, as engraved on one of those silver relics, appears to be the head of a dog or some other animal.

The earlier of the Scottish sculptured stones, such as the Maiden Stone in Aberdeenshire, and the older of the stones at Aberlemno, have no sculptures except of the class above described; the later combine these with devices of a more intelligible kind. An elephant is not unfrequent, represented in such a fashion, that it is obvious that the artist could never have seen one; and fabulous and grotesque figures abound, often drawn with considerable spirit. We have centaurs, lions, leopards, deer, beasts of chase, men shooting with a bow and arrow, men devoured by animals, processions with men and oxen, and priests in their robes with books. Many of

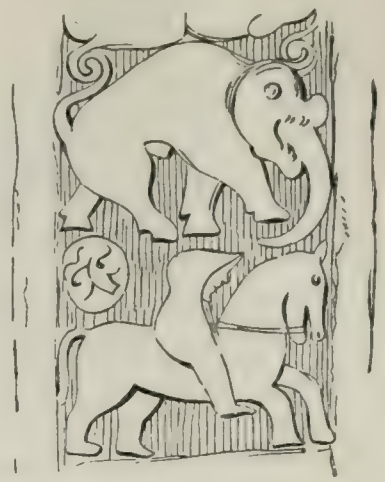

Fig. 2.—Part of Sculptured Stone—Island of Ellanmore, Argyleshire.

these figures are highly interesting illustrations of the manners, customs, and dress of the period. On a stone near Glammis is a man with a crocodile's head. On the cross at St Vigeans, a hybrid, half-bird half-beast, appears in the midst of a border of entwining snakes and fantastic creatures. A stone of great interest at Meigle contains a representation of a chariot. At Farnell is a group of figures that seems to be meant for the temptation. In but two instances have inscriptions been known to accompany these sculptures; in the one case the letters are so worn away as to be undecipherable; in the other instance, at St Vigeans, a few letters can be traced of the same Celtic character which has been found on the earliest Irish monuments and the oldest tombs at Iona.

The general style of ornamentation of these stones, judging by a comparison with Anglo-Saxon illuminated MSS., has led to the conclusion that they were erected in the 8th or 9th c., a period when Christianity had but lately supplanted paganism among the Scottish Picts.

A stone differing in character from those described, now erected near the House of Newton in Aberdeenshire, in the same neighbourhood in which it was found, has been a notable puzzle to archæologists. It is not sculptured, but inscribed in a character which seems unique. Besides the principal inscription, there is another running along the edge, consisting of groups of short lines, and apparently in the Ogham (q. v.) character.

The crosses in Ireland are the likest to these Scottish monuments. They are chiefly found near churches and graveyards, and are generally cruciform, with a halo or circle binding the arms and stem together. They usually taper to the top, on which a conical capstone is fixed, and they are inserted in pedestals of stone, which are frequently covered with sculpture. Most of their subjects are from Scripture history, without anything like the Scotch symbols.

The Welsh crosses are, for the most part, in the form of a small cross within a circle, set on the top of a long shaft, the latter having at times interlaced ornaments in compartments. Many of them have inscriptions in the Romano-British character, relating to the persons in memory of whom they were erected.

The sculptured crosses of Scandinavia and Man somewhat resemble the Scotch monuments in their

general style of ornamentation, though altogether destitute of the peculiar Scottish symbols. On some of them are Runic inscriptions. One inscription on a Manx cross indicates that Gaut (probably a Norwegian) made this cross and all on Man. Another is to the effect that ——— erected this cross to his father Ufag, but Gaut Bjornson made it. Professor Munch, from the character of the Runes on these crosses, assigns them for date the middle or end of the 11th century. See RUNES.

A hundred and fifty of the sculptured stones of Scotland have been carefully engraved and described in a very valuable work contributed to the Spalding Club by Mr John Stuart. Some of those belonging to the county of Angus had been previously illustrated by the late Mr Chalmers of Auldbar, in a volume forming one of the Bannatyne Club series.

SCUPPERS are holes, lined with lead, in a ship's side, intended to carry off rain or other water which may be shipped.

SCURVY, or SCORBU'TUS, is a disease which is characterised by a depraved condition of the blood. In consequence of this morbid state of the blood, there is great debility of the system at large, with a tendency to congestion, hæmorrhage, &c., in various parts of the body, and especially in the gums. It is a disease that has probably existed from the earliest times, but the first distinct account of it is contained in the history of the crusade of Louis IX., in the 13th c., against the Saracens of Egypt, during which the French army suffered greatly from it. In the 16th c. it prevailed endemically in various parts of the north of Europe, and it seems only to have abated about a century ago. It was in badly-fed armies, in besieged cities, and on board ship, that its ravages were most appalling, and it is believed that more seamen perished from scurvy alone than from all other causes combined, whether sickness, tempest, or battle. Whole crews were prostrated by this scourge, as in the well-known case of Lord Anson's memorable voyage.

Scurvy so closely resembles purpura in its general symptoms that it will be sufficient for us to refer to the article on that disease, and here merely to indicate the leading points of difference between the two diseases, which, notwithstanding their similarity, are essentially different. Scurvy is caused by a privation, for a considerable time, of fresh succulent vegetables, while purpura often makes its appearance when there has been no deficiency of this food, or special abstinence from it. Scurvy is most common in winter or the early spring, while summer and autumn are the seasons for purpura. In scurvy the gums are invariably swelled and spongy, and bleed readily; in purpura this is not necessarily the case. In scurvy there is extreme debility and depression of spirits, venesection and mercury do positive harm, while a cure is rapidly effected by the administration of lemon-juice, or of fresh fruits and vegetables; whereas in purpura there is little or no mental or bodily depression, venesection and mercury often give relief, while no marked and certain relief follows the administration of the lemon-juice and fruits that are all powerful in scurvy.

Although the virtues of lemon-juice in scurvy were known in Great Britain as far back as 1636, when John Woodhall, Master in Surgery, published *The Surgeon's Mate, or Military and Domestic Medicine*, this invaluable medicine was not made an essential element of nautical diet till 1795. The effect of this official act may be estimated from the following numbers. In 1780 the number of cases of scurvy received into Haslar Hospital (a purely naval hospital) was 1457, while in 1806 there was only one case, and in 1807 only one case. Many naval surgeons of the present day have never seen a case of the disease. The potato possesses almost equally great antiscorbutic properties, and, fortunately, potatoes when cooked are as active as when taken raw. The late Dr Baly, to whom we are indebted for this discovery, states that 'in several prisons the occurrence of scurvy has wholly ceased on the addition of a few pounds of potatoes being made to the weekly dietary.' The salutary action of potatoes is probably owing to their containing a considerable amount of tartaric acid, partly in combination with potash and lime, and partly free. In addition to the dietetic treatment, which should include easily-digested animal food, potatoes, such ripe fruits as can be procured, and an abundance of lemonade, little further need be prescribed. If necessary, constipation must be relieved by mild laxatives, such as rhubarb and castor-oil; the appetite may be stimulated by bitter tonics, and opiates given to procure rest in cases of pain or obstinate wakefulness. When the gums are very troublesome, solutions of tannin, chloride of lime, or of nitrate of silver, may be applied to them. For an excellent account of this disease, the reader is referred to the article 'Scurvy' by Dr Budd, in *The Library of Practical Medicine.*

SCURVY-GRASS (*Cochlearia*), a genus of plants of the natural order *Cruciferæ*, having small white flowers, and turgid many-seeded pouches; the cotyledons accumbent. The species are annual or biennial, rarely perennial, plants; of humble growth, with branched smooth stems, smooth simple leaves, and terminal racemes of flowers. They have an acrid biting taste, containing the same pungent volatile oil which is found in horse-radish, and are valued for their antiscorbutic properties. COMMON S. (*C. officinalis*) is sometimes a foot high; the root-leaves are stalked and heart-shaped; the pouches globose, ovate, or elliptical. It is a variable plant, and some of the other species described by botanists are probably not essentially different. They possess the same properties. S. is very common on the shores of Britain, growing both on rocks where there is little soil, and in muddy places. It is also found on high mountains. It is a very widely-distributed plant, and being found on the shores of almost all parts of the world, has often been of the greatest benefit to sailors, in times when the modern precautions against sea scurvy were unknown.

SCU'TAGE, or ESCUAGE (Lat. *scutum*, shield), a pecuniary fine or tax sometimes levied by the crown, in feudal times, as a substitute for the personal service of the vassal. No scutage seems at any time to have been levied in Scotland.

SCU'TARI (Italian or Levantine form of the Turkish *Usküdar*), a town of Asiatic Turkey, on the eastern shore of the Bosporus, immediately opposite Constantinople, of which it may be considered a suburb. It is built on the sides and summit of a hill, sloping irregularly upwards from the water's edge, and bears, both externally and internally, a great resemblance to the Turkish capital. It contains several mosques, bazaars, and baths, a college of howling dervishes, manufactories of silks and cotton fabrics, corn warehouses, and *imarets* or kitchens for the poor. It has long been famed for its extensive cemeteries, adorned with magnificent cypresses, the chosen resting-place of many of the Turks of Constantinople, from attachment to the sacred soil of Asia, and the traditionary belief that their race will one day be driven out of Europe. The population is variously estimated at from 40,000 to 60,000, or even 100,000. S. has

of late years acquired great notoriety in connection with the English army during the Russian War (1854—1856), when the enormous barracks built by Sultan Mahmud, on the southern outskirts of the town, were occupied as barracks and hospital by the English troops, and formed the scene of Miss Nightingale's labours. A little to the south of the General Hospital, on the cliffs bordering the Sea of Marmora, is the densely-filled English burial-ground, where Baron Marochetti's monument in honour of the troops has lately been erected.—S. is a place of considerable traffic, and is the rendezvous and starting-point of caravans and travellers trading with the interior of Asia. It occupies the site of the ancient *Chrysopolis;* and about two miles to the south, lies the village of Kadiköi, the ancient *Chalcedon.*

SCUTARI (Turkish *Iskandere*, the anc. *Scodra*), a considerable town of European Turkey, in Northern Albania, capital of a sanjak of the same name, situated at the southern end of the Lake of Scutari, at the point where the Bojana, issuing from it, is joined by the Drinassi. The lake is about 20 miles long, and abounds in fish. S. is a fortified town, with a citadel on a commanding height. It has manufactories of arms and cotton goods a bazaar, and yards for building coasting-vessels It carries on a considerable trade. The population is estimated at about 40,000, of whom about one half are Roman Catholics.

SCUTCHEON, in Carpentry, is the small metal plate used to form the protection and ornament to the keyhole for locks; it is usually of brass, but in ornamental cabinet-work, is often of ivory, mother of pearl, &c. See SHIELD.

SCY'LLA AND CHARY'BDIS. Scylla (Gr. *Skullaion*), a rocky cape on the west coast of South Italy, jutting out boldly into the sea so as to form a small peninsula just at the northern entrance to the Straits of Messina. About the beginning of the 5th c. (B.C.), a fort was built upon the rock (which is about 200 feet high, and much hollowed out below by the action of the waves), and in course of time a small town grew up, straggling down the slopes towards the sea. The navigation at this place was looked upon by the ancients as attended with immense danger, which, however, seems to have been much exaggerated, for at the present day the risk is not more than attends the doubling of any ordinary cape. The rock, according to the Homeric legend, was the abode of a monster called Scylla, possessing 12 feet, 6 long necks and mouths, each with three rows of sharp teeth, and who barked like a dog. There are other accounts of Scylla, one of which represents her as having once been a beautiful maiden, beloved by the sea-god Glaucus, but who, by the jealousy of Circé, was changed into a monster having the upper part of the body that of a woman, while the lower part consisted of the tail of a fish or serpent surrounded by dogs. The modern Scilla or Sciglio is a fortified town in the province of Reggio-Calabria, having large silk-works, the pop. being upwards of 7400, mostly seafaring people.

Charybdis (modern name *Galofaro*), is a celebrated whirlpool in the Straits of Messina, nearly opposite the entrance to the harbour of Messina in Sicily, and in ancient writings always mentioned in conjunction with Scylla. The navigation of this whirlpool is, even at the present day, considered to be very dangerous, and must have been exceedingly so to the open ships of the ancients. A modern writer describes it as being 'an agitated water of from 70 to 90 fathoms in depth, circling in quick eddies.' Homer places it immediately opposite to Scylla, probably taking advantage of the poetic licence to exaggerate the danger of the navigation, although it is not improbable that the whirlpool may have changed its situation since his days. The myth connected with it is, that under a large fig-tree, which grew out of a rock opposite Scylla, dwelt the monster Charybdis, who thrice every day sucked down the water of the sea, and thrice threw it up again.

SCYTHE. See REAPING.

SCY'THIA, a name employed in ancient times to denote a vast, indefinite, and almost unknown territory north and east of the Black Sea, the Caspian, and the Sea of Aral. But the term is not so much *geographical* as *ethnological*, and the only interest attaching to the barren catalogue of tribes and nations, which we meet with in the classical writers, springs from the hope of connecting these with a recognised race of modern times. Latham argues—successfully, as it appears to us—for the Scythians being the ancestors of the later *Turks*, and maintains their central and primitive abode to have been Independent Tartary, whence they spread west round the Caspian into Russia, Transylvania, and perhaps even Eastern Hungary. Niebuhr and Neumann favour the hypothesis of a Mongol origin for the Scythians; while others regard them as Finns or Circassians. In their mode of life they were mainly nomadic and pastoral, though we read of some trans-Danubian and Euxine tribes that followed agriculture. Many of them were *Hippemolgi* ('mare-milkers').

SEA, in its general signification, denotes that large expanse of salt water which covers the more depressed portion of the earth's surface, fills up each hollow and rift to a certain uniform level, completing as far as possible the spheroidicity of the globe, and divides its surface into two great and innumerable smaller portions—the Old and New Worlds and their islands. This immense body of water is not distributed with the least approach to regularity, but here forms a huge basin, there becomes a long and tortuous inlet or strait, which narrows or widens as the configuration of the land-surface on each side permits; nor is it placed symmetrically to the earth's axis of rotation; for the hemisphere of which the south-west corner of England is the centre or pole contains the whole of the land-surface, if we except the triangular portion of South America, south of Uruguay, Australia, New Zealand, the most of the East Indian Islands, and the land around the south pole (of unknown extent). The other hemisphere is, with these exceptions, wholly water. From this irregular distribution of the sea over the earth's surface, and from the specific gravity of water being about $\frac{1}{6}$th of that of the land, it necessarily follows that the centre of gravity of the whole globe does not correspond accurately with its centre of figure. The extent of sea-surface is estimated at 146,000,000 English sq. m., or nearly $\frac{3}{4}$ths of the whole of the earth's surface, and its mass, on the supposition of an average depth of 4½ miles, is more than $\frac{1}{1800}$th of that of the whole globe; such estimates, however, can be considered at best as only rough approximations. One of the most remarkable features of the sea is its continuity or oneness; for in spite of the fact, that numerous large stretches of salt-water, as the Sea of Azof, Black, Mediterranean, and Baltic Seas, the Gulf of Mexico, and others, have barely avoided becoming detached lakes, very few such are found on the earth's surface; and with the exception of the Caspian and Aral Seas, they are of small size.

Composition, Specific Gravity, and Temperature of

the Sea.—The sea consists of salt water, and from its continual motion, under the influence of currents and waves, preserves, generally speaking, uniform saltness. Under special circumstances, however, we find the saltness increased, as by the excess of evaporation over the fresh-water influx in the Mediterranean and Red Seas, and about the northern and southern limits of the tropical belt; and decreased, by the contrary cause, in the Sea of Azof, Black Sea, Baltic Sea, and in the polar regions. See TRADE-WINDS. The origin of the saltness of the sea is sufficiently accounted for when we consider, that the chloride of sodium and other soluble salts which form constituent ingredients of the globe, are being constantly washed out of the soil and rocks by rain and springs, and carried down by the rivers; and as the evaporation which feeds the rivers carries none of the dissolved matter back to the land, the tendency is to accumulate in the sea. The principal ingredients found in sea-water are chloride of sodium, or common salt, together with salts of magnesia and lime. A more exact analysis will be given under WATER. The average specific gravity of the sea, out of reach of the exceptional action of the melting of snow, rain or river water, is (at 62° F.) 1·0272. The slight variations in the saltness of the sea must necessarily produce corresponding changes in its specific gravity; accordingly, on the northern and southern limits of the torrid zone, the mean specific gravity of the sea is, in different longitudes, 1·0281, 1·0294; while at the equatorial calm belt, it is 1·0272, 1·0279; and on the whole shews a tendency to diminish as the latitude increases, Beechey having found it to be 1.0258 in lats. 55°—60° N. and S. in the Pacific, and King 1·0255 in the corresponding latitudes of the Atlantic. It also increases with the depth below the surface, though not at a regular rate; is considerably diminished by rains at and near the mouths of rivers, and in those inlets or semi-lacustrine arms which are the depositories of more river-water than compensates for their evaporation, as in the Black Sea, where it is only 1·0141. A few springs of fresh water are found in the sea, but their effect in diluting its saltness is infinitesimal.

The temperature of the sea, where it is not affected by currents from a warmer or colder region, necessarily corresponds to that of the air above it; but this is true only of the water at and near the surface, for it has been found, that beyond a certain limit of depth, the temperature is constant at 39° to 39·5° F. This depth, however, is not the same at all latitudes, but appears to vary in a similar manner to the perpetual snow-line on land—being about $1\frac{2}{5}$ths miles under the equator, thence gradually rising to the surface, which it reaches (in the southern hemisphere) in lat. 56° 25′, and in the northern hemisphere in lat. 48° 20′—67° 30′, the limits of the isotherm of 39°—39° 5′, and descending as the latitude increases to $\frac{6}{7}$ths of a mile about lat. 70°. From the equator to the isotherm of 39°, the water above this line is warmer, and between this latitude and the pole is colder than it is below the line, the temperature gradually, though not uniformly, varying from the line to the surface. Of course, in a few localities where exceptional causes are at work, as in the case of the sea between Corunna and Ferrol, as found by Humboldt, violations of this rule may occur, but these are comparatively few in number. The line of greatest surface-temperature does not correspond to the equator, but, owing to the disturbing influence of currents, is found in lat. 10° N. in the Atlantic (28° N. in the Gulf of Mexico), lat. 12° N. in the Indian Ocean, and lat. 8° S. in the Pacific. See ISOTHERMAL LINES. The temperature of the surface on sea is far less variable than it is found to be on land, and there exist extensive tracts, especially in the North Atlantic and North Indian Oceans, where it is almost equable.

Colour and Phosphorescence of the Sea.—The colour of the ocean, when free from admixture of foreign substances, as animalcules, vegetable organisms, excessive rain, or the tinted waters of swollen rivers, is a pure deep blue, which becomes less marked where the water is of less depth. The origin of this colour is sought in the fact, that the blue rays of the spectrum are less liable to be absorbed by masses of transparent fluid than are the others, and thus predominating in the reflected pencil, they make most impression on the eye. This hypothesis is certainly supported by the numerous instances in which it has been well ascertained that a 'different' colour of sea-water is due to the presence of some foreign substance, e. g., the red, brown, and white patches of the Pacific and Indian Oceans, to the presence of swarms of animalcules, and the colours of the Red and Yellow Seas, to matters of vegetable origin. However, some fresh-water lakes exhibit the same phenomenon, while others, for no ascertained reason, do not; and the Rhone, at its emergence from the lake of Geneva, exhibits an intensity of blue far surpassing that of any sea. The probability is that we have only got hold of a part of the explanation. The phosphorescence of the sea is due to the presence of myriads of invertebrata, especially rhizopoda, tunicata, &c. See LUMINOSITY OF ORGANIC BODIES.

Depth of the Sea.—Till very recently, it might be said that, with the exception of the more frequented strips along the coast, and such other portions as afforded anchorage-ground, our knowledge of the depth of the ocean amounted to nothing. It is true that deep-sea soundings had been frequently made, but from the necessary defectiveness of the ordinary 'lead,' and inattention to the effect of under-currents in destroying the perpendicularity of the line, little dependence could be placed on the results obtained. Even at the present time, our knowledge is confined chiefly to the North Atlantic, the greatest depth of which, as far as it has (according to Maury's opinion) been satisfactorily ascertained, is 25,000 feet, though there are, in all probability, considerably greater depths in the region between the United States, the Bermudas, and Newfoundland. Soundings giving a depth of $2\frac{1}{2}$ and of more than 3 miles were made by Lieutenant Brooke in the Pacific, and this result corresponded very nearly with the estimate of its average depth drawn by Professor Bache from observation of the time taken by the great tide-waves of December 23, 1854, originated by the terrible earthquake which occurred in Japan on that day, to traverse the ocean between Japan and California; the latter giving an average depth of 2365 fathoms, or $2\frac{11}{16}$ miles. From the numerous islands which stud this ocean, one would be led at first sight to assume its comparative shallowness; but the abruptness with which they rise above the surface, and the remarkable soundings which have been obtained near their shores, completely annihilate this supposition. In the Indian Ocean, Brooke made a sounding of about 8 miles, but Maury (who strenuously opposes the old belief in the great depth of the sea) throws great doubt on the correctness of this result. From the remarkable gentleness of slope of the bed of the Arctic Ocean to the north of Siberia, the line giving only 14—15 fathoms at 150 miles from the shore, and from its configuration on the north of America, it is generally concluded to be by far the shallowest of the oceans, but no one

has hitherto ventured to give a deliberate estimate of its depth. Of the depth of the Antarctic Ocean, nothing is *known*, but it is supposed to be deeper than its antipodal kinsman. Till our chart of soundings be tolerably complete, it will be impossible to give any general idea of the conformation of the bed of the sea, but, judging from what has been lately discovered concerning the North Atlantic (q. v.), it would seem as if the land-surface under water were the counterpart as regards eminences and hollows, chasms, valleys, plateaus, &c., of the land-surface above.

Motion of the Sea.—The sea is in a state of perpetual restlessness, its motion being either a vertical oscillation, or an actual transference of its waters from one place to another. The first motion, which constitutes *waves*, is due either to the attraction of the sun and moon on such a mobile body as the sea (see TIDES), or to the impulsive action of the winds which blow over its surface (see WAVES); the second arises from the sun, which, directly through its heat, and indirectly by scorching dry winds, produces evaporation to a great extent, of the parts most exposed to its influence, and by its similar action on the atmosphere (see TRADE-WINDS), causes a transference of this vapour to remote latitudes, where it descends as rain, and, destroying the equilibrium of the sea, gives rise to *currents*. The nature of these currents is described under GULF STREAM, and the chief currents of each ocean are found under its own head. This constant motion of the sea is of great service in tending to equalise the temperature of different parts of the globe; it also produces remarkable changes in the form of coasts, eating into rocks, converting low-lying lands into shoals and sand-banks, or carrying away the earthy materials, and depositing them in some distant region. The erosive action of the sea is generally almost imperceptible during several years, but in course of two or three centuries, the magnitude of the changes effected by it is almost incredible.

The sea, like the land, teems with animal life; representatives of the four great divisions of the animal kingdom are found abundantly, and though its temperature is far more equable, the limitation of the zonal range of animals is not a whit less definite: the profound depths of ocean would appear to be as barren of vegetable and animal life as are the lofty summits on land; and the inhabitants of the deep seem to suffer as much from being taken even a little out of their depth, as would a land animal removed to an unaccustomed altitude.

On the economic value of the sea as a purifier, and as a commercial highway, it is unnecessary to dilate. For some of the peculiar phenomena of the sea, see ICEBERGS, AURORA BOREALIS, WHIRLPOOLS, the five great OCEANS (q. v.), CORAL, &c.

The term *Sea* is also applied in a more limited though indefinite sense, to an offshoot of one of the oceans, as to the Black, Baltic, Okhotsk Seas, to any portion of an ocean which from its position or configuration is considered deserving of a special name, and to the two great inland salt lakes of Central Asia, the Caspian and Aral Seas.

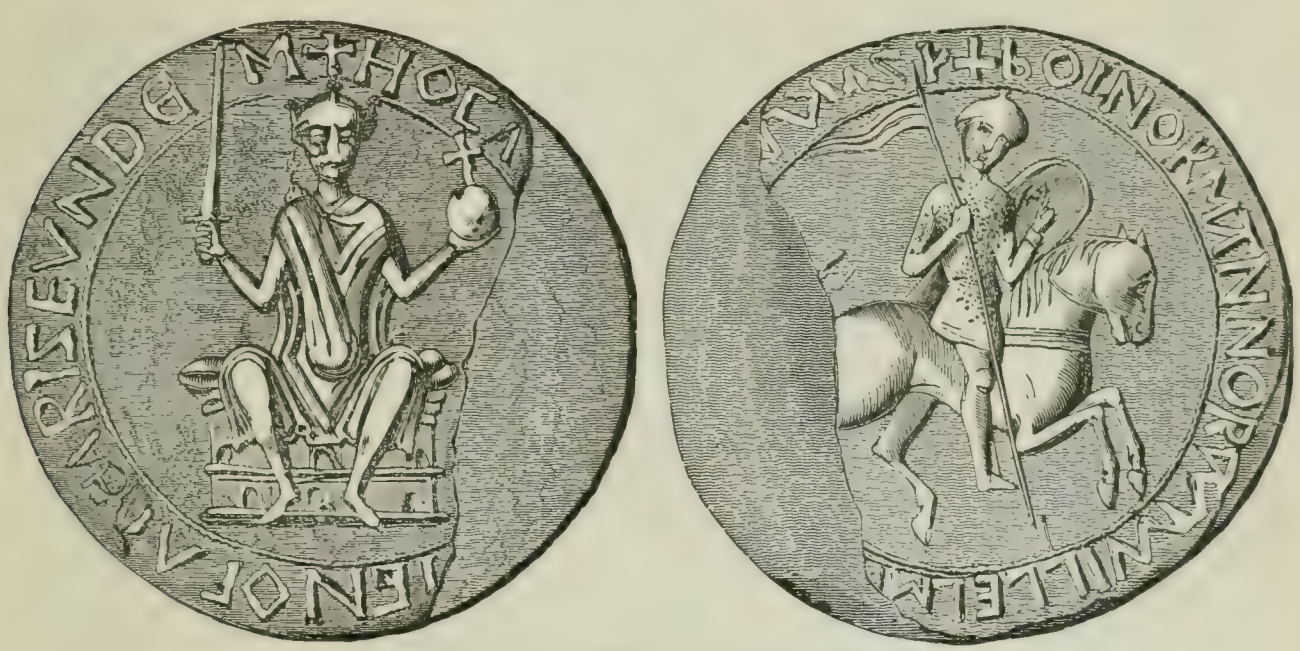
SEA, SOVEREIGNTY OF THE. Blackstone lays it down that the main or high seas are part of the realm of England, as the Courts of Admiralty have jurisdiction there; but adds that they are not subject to common law. But the law of nations, as now understood, recognises no dominion in any one nation over the high seas, which are the highway of all nations, and governed by the public law of the civilised world. Such a right has, however, long been claimed over the four seas surrounding the British Isles. It was strongly asserted by Selden, and denied by Grotius, and measures were taken to vindicate the right in the reign of Charles I. Every nation has undoubtedly a right to the exclusive dominion of the sea within a certain not very well-defined distance from the shore, depending on the usage of the country. This right of lordship includes the right to free navigation, to fishing, to taking wrecks, the forbidding passage to enemies, the right of flag, of jurisdiction, &c. By the law of England, the main sea begins at low-water mark; and between low and high-water mark the common law and admiralty have a divided jurisdiction, one on land when left dry, the other on the water when it is full sea. By the law of Scotland, the sea-shore is not considered to extend beyond the point which the sea reaches in ordinary tides. See BLOCKADE, NEUTRALS.

SEA CUCUMBER. See HOLOTHURIA.

SEA GRAPE (*Ephedra*), a genus of plants of the natural order *Gnetaceæ*, a natural order consisting of a small number of species, closely allied in botanical characters to the *Coniferæ*, and by many botanists united with that order, although differing much in appearance. The *Gnetaceæ* are small trees, or twiggy shrubs, with opposite or clustered branches and jointed stems, whence they are sometimes called JOINT-FIRS. They secrete not resinous but watery matter. The development of the ovule is very peculiar; it has a projecting process formed from the intimate covering of the nucleus.

SEAHAM HARBOUR, a thriving seaport in the county of Durham, 6 miles south of Sunderland. Its excellent harbour is furnished with wharfs, quays, and jetties, and the town contains most extensive bottle-works, blast furnaces, iron-foundry, and chemical works. It communicates by railway with collieries in the vicinity, and the principal articles of export are coals and agricultural produce. The town nearly doubled its population between the years 1855 and 1865. Pop. (1851) 3538, (1861) 6137, (1865) 7000.

Sea-horse.



SEA-HORSE, in Heraldry, a fabulous animal, consisting of the upper part of a horse with webbed feet, united to the tail of a fish. A scalloped fin is carried down the back. The arms of the town of Cambridge are supported by two sea-horses, proper finned and maned or.

SEA-KALE (*Crambe maritima;* see CRAMBE), a perennial plant with large roundish sinuated sea-green leaves, found on the sea-shores in various parts of Europe, and in Britain. The blanched sprouts have become a very favourite esculent in Britain, although as yet little known on the continent. The common people, on some of the shores of England, had long been in the practice of watching them when they came through the sand, and using them as a pot-herb, but the cultivation of the plant in the kitchen garden became general only at a comparatively recent date. It requires a deep rich soil, and the care of the gardener is bestowed upon the blanching, without which the sprouts are not tender and agreeable, but even acrid. The blanching is accomplished in various ways, by earth, sand, boards, earthenware pots, &c. Sea-kale is generally raised from seed, although also sometimes propagated by offsets or by cuttings of the roots. The seedlings do not yield a crop till the third year; but a plantation of sea-kale remains productive for many years.

It is planted in rows, four to six feet apart. It sends its tap-root very deep into the ground.

SEAL (Lat. *sigillum*, Fr. *sceau*), an impression on wax or other soft substance made from a die or matrix of metal, a gem, or some other material. The stamp which yields the impression is sometimes itself called the seal. In Egypt, seals were in use at an early period, the matrix generally forming part of a ring (see GEM, RING). Devices of a variety of sorts were in use at Rome, both by the earlier emperors and private individuals. The emperors, after the time of Constantine, introduced *bullæ* or leaden seals, and their use was continued after the fall of the Western Empire by the popes, who attached them to documents by cords or bands. On the earlier papal seals are monograms of the pope; afterwards the great seal contained the name of the pope in full, and a cross between the heads of St Peter and St Paul, while the papal privy seal, impressed not on lead but on wax, known as the *Seal of the Fisherman*, represented St Peter fishing. In the 9th and 10th centuries we find Charlemagne, the Byzantine emperors, and the Venetian doges, occasionally sealing with gold, and we have an instance as late as the 16th c. of a gold seal appended to the treaty of the Field of the Cloth of Gold, between Henry VIII. and Francis I.

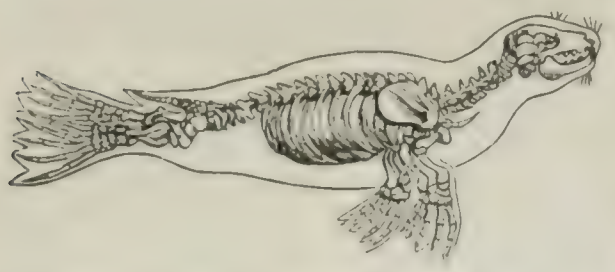
Seals were not much used in England in Anglo-Saxon times, but they came into general use after the Norman Conquest. On the royal great seals was the king in armour on a caparisoned horse galloping, his arms being shewn on his shield after the period when arms came into use; and the reverse represented the king seated on a throne. The great seals of Scotland begin with Duncan II.

Great Seal of William the Conqueror.

in the end of the 11th c., and have also for subject the king on horseback; the counterseal, with the seated figure, being used first by Alexander I., and the earliest appearance of the arms of Scotland being on the seal of Alexander II. In both countries there were also the privy seals with the royal arms only.

Ecclesiastical seals first appear in the 9th c., and attained great beauty in the 13th and 14th. They are of the pointed oval form known as *Vesica piscis*; and have for subjects, a figure of the bishop, sometimes of the Trinity, the Virgin, or a patron saint, seated under an elaborate architectural canopy. The arms of the bishop are often added.

Under the Norman monarchs of England, sealing became a legal formality, necessary to the authentication of a deed; and from the 13th c. onwards, the seals of all persons of noble or gentle birth represented their armorial ensigns. The seal was generally appended to the document by passing a strip of parchment or a cord through a slit in its lower edge; and the ends being held together, the wax was pressed or moulded round them a short distance from the extremity, and the matrix impressed on it. Occasionally the seal was not pendant, but the wax was spread on the deed. The coloured wax with the impression was sometimes imbedded in a mass of white wax forming a protective border to it. In England, a seal is still an essential to all legal instruments by which real estate is conveyed; but since subscription has also become necessary, the practice of sealing has degenerated into a mere formality. The custom was gradually introduced of covering the wax with white paper, on which the impression was made, and latterly wafers have been considered a sufficient substitute for seals.



In Scotland, every freeholder was obliged by statutes of Robert III. and James I. to have his seal of arms, an impression of which was kept in the office of the clerk of court of the shire; and among the Scottish armorial seals of the 14th and 15th centuries are some of wonderful beauty of execution. Act 1540, c. 117, for the first time made subscription an essential formality to deeds; but sealing still continued to be necessary till 1584, when it was dispensed with in the case of deeds containing a clause of registration, and soon afterwards the practice was altogether laid aside.

The use of corporate seals by towns and boroughs dates as far back as the 12th century. The earlier corporate seals bear the town gates, city walls, or some similar device; the use of corporate arms did not begin till the latter half of the 14th century.

The principal use of seals in the present day is in closing letters, and even for this purpose they have of late years been less used than formerly, owing to the fashion of using stamped adhesive envelopes.

The study of medieval seals is of great importance and interest in connection with many branches of archæology, including heraldic and genealogical investigations. See GREAT SEAL; PRIVY SEAL.

SEAL (*Phoca*), a Linnæan genus of Mammalia, now forming the family *Phocidæ*, and including all that family except the Morse (q. v.), or Walrus. The name S. is from the Anglo-Saxon *Seol*. The *Phocidæ* constitute, in Cuvier's system, a section of *Carnivora* (q. v.) designated *Amphibia*. Their

Skeleton of Seal, with outline of the figure.

structure is most perfectly adapted to an aquatic life, and they live chiefly in water, but spend part of their time on shore, reposing and basking in the sunshine on rocks, sand-banks, icefields, or beaches; and they bring forth their young on shore. The body is elongated, and tapers from the chest to the tail; the head somewhat resembles that of a dog, and in most of the species the brain is large; the feet are short, and little more than the paw projects beyond the skin of the body; all the feet are thoroughly webbed, and five-toed; the fore-feet are placed like those of other quadrupeds; but the hind-feet are directed backwards, like a prolongation of the body, and between them is a short tail. The toes, particularly those of the hind-feet, are capable of being spread out very widely in swimming, so as to give great propulsive power. The movements of seals in the water are very rapid and graceful; on land, they are very peculiar; even the fore-feet being little used or not at all, but the body contracted by an upward bending of the spine, and so thrown forward by a succession of jerks; in which way, however, a S. makes its escape very rapidly from an assailant. The flexibility of the spine in seals is very remarkable, and depends on the very large intervertebral cartilages, formed of fibrous concentric rings. The muscles, which are connected with the spine on all sides, are of great strength.

The teeth differ considerably in the different genera, but in all are adapted for the seizure of slippery prey, the chief food of seals being fishes, although they do not reject other animal food, and are said even to feed in part on vegetable substances. Their incisors are either six in the upper jaw and four in the lower, or four in the upper and two in the lower; they all have large and strong canine teeth; and the molars, usually five or six on each side in each jaw, are either sharp-edged or conical, and beset with points. Seals have a remarkable habit of swallowing large stones, for which no probable reason has yet been conjectured. Their stomachs are very often found to be in part filled with stones. The stomach is quite simple; the gullet (*œsophagus*) enters it at the left extremity; the cæcum is short, the intestinal canal long.

The respiration of seals is extremely slow, about two minutes intervening between one breath and another, when the animal is on land and in full activity. A S. has been known to remain twenty-five minutes under water. Their slowness of respiration, and power of suspending it for a considerable time, are of great use, as enabling them to pursue their prey under water. The fur of seals is very smooth, and abundantly lubricated with an oily secretion. There is generally an inner coating of rich fur, through which grow long hairs, forming an outer covering. Another adaptation to aquatic life and cold climates appears in a layer of fat immediately under the skin—from which *Seal Oil* is obtained—serving not only for support when food is scarce, but for protection from cold, and at the same time rendering the whole body lighter. The nostrils are capable of being readily and completely closed, and are so whilst the S. is under water; and there is a similar provision for the ears; whilst the eye, which is large, exhibits remarkable peculiarities, supposed to be intended for its adaptation to use both in air and water. The face is provided with strong whiskers, connected at their base with large nerves.

Seals produce their young only once a year; sometimes one, sometimes two, at a birth. Not long after their birth, the young are conducted by the mother into the sea. Many, if not all, of the species are polygamous. Terrible fights occur among the males.

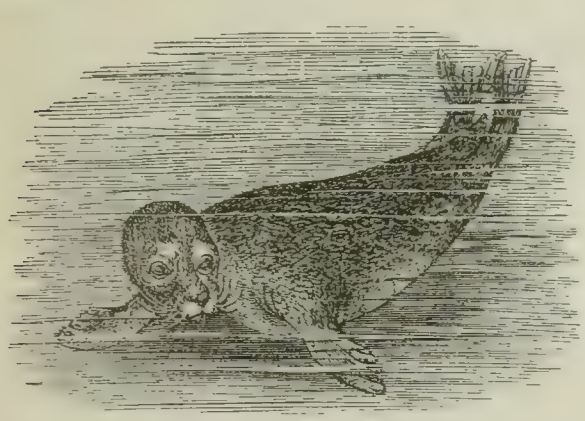
Seals are very much on their guard against the approach of man, where they have been much molested; but where they have been subjected to no molestation, they are far from being shy, and approach very close to boats, or to men on shore, as if animated by curiosity. They are much affected by musical sounds. A flute is said to attract seals to a boat, where they have not learned caution from sore experience; and the ringing of the church bell at Hoy, in Orkney, has very often caused the appearance of numerous seals in the little bay. Seals possess all the five senses in great perfection.

The Common S. and some of the other species are very intelligent; but there is considerable difference in this respect among the species. The Common S. and some others have often been tamed, and are capable of living long in domestication, if freely supplied with water. They become very familiar with those who attend to them, are very fond of caresses and of notice, recognise their name like dogs, and readily learn many little tricks, of which advantage has been taken for exhibitions.

Seals are found in all the colder parts of the world, most abundantly in the arctic and antarctic regions; some of them also in temperate climates, as far south as the Mediterranean, and as far north as the La Plata. Some of them ascend rivers to some distance in pursuit of salmon and other fish. They are found in the Caspian Sea, and even in the fresh-water Lake Baikal.

The species are numerous, but in no group of Mammalia does more remain for further investigation. Seals are divided into two principal groups—*Seals*, more strictly so called, and *Otaries* (q. v.); the former distinguished by the complete want of external ears, which the latter possess, and by their dentition. The true seals have been further subdivided into genera, chiefly characterised by their dentition. In the restricted genus *Phoca*, or *Calocephalus*, the incisors are pointed and sharp-edged, six above and four below. The Common S. (*Phoca vitulina*) is found in the northern parts of the Atlantic Ocean, and in the Arctic Ocean. It is common on the wilder and more unfrequented parts of the British coast, particularly in the north. It is remarkably distinguished, even among its nearest congeners, by the oblique position of the molar teeth. The fur is yellowish, variously spotted, and marked with brown. The whole length is from 3 to 5 feet. Its love of salmon is so great that it has been known to haunt the neighbourhood of a salmon-net for a long time, and to take the fish after they were entrapped in it. The Common S. is generally seen in small herds. Its skin and oil are of considerable mercantile importance. The skin is dressed with the fur on, to make caps, &c., or is

Vol. VIII., page 584.



SEALS.

tanned and used as leather. The oil, when made before decay has begun, is colourless and nearly inodorous; it is much superior to whale-oil. The flesh is much used for food in very northern countries, as is that of all the other species which they produce. It is not easy to shoot a seal. Whilst flint-locks were in use, the S. always dived so quickly on seeing the flash as generally to escape the ball. The popular name SEA-CALF, and the specific name *vitulina*, have reference to a supposed resemblance of the voice to that of a calf.—The HARP S. (*P. Grœnlandica*) receives its popular

Harp Seal (*Phoca Grœnlandica*), attitude on land.

name from a large, black, crescent-shaped mark on each side of the back. It is sometimes seen on the British coasts, but belongs chiefly to more northern regions. It is from 6 to 8 or even 9 feet in length. —The GREAT S., or BEARDED S. (*P. barbata*), also found on the British coasts, and plentiful on the coasts of Greenland, is generally about 9 or 10 feet long, sometimes more.—The ROUGH or BRISTLED S. (*P. hispida*) frequents quiet bays on the coasts of Greenland, where many thousands are annually killed for their skins and oil. It is the smallest of the northern species.—The GRAY S. (*Halicherus griscus*), which has a very flat head, and attains a

Common Seal (*P. vitulina*), attitude when swimming.

size nearly equal to the Great S., occurs on the British coasts, but is much more common in more northern latitudes, and in the Baltic Sea.—The CRESTED S. (*Stemmatopus cristatus*) is remarkable for the elevation of the septum of the nose of the adult male into a crest, which supports a hood covering the head, and capable of being distended and elevated or depressed at pleasure. The use of this appendage is not known. This S. is plentiful on the coasts of Greenland and the northern parts of North America.—The seals of the southern seas are quite distinct from those of the northern. One of them is the SEA LEOPARD, or LEOPARD S. (*Leptonyx Weddellii*), so called from its spotted fur. It is found on the South Orkneys and other very southern islands. By far the largest of all the seals is the ELEPHANT S. or Sea Elephant of the southern seas. See ELEPHANT, SEA.

Seals are to some extent migratory, although their migrations do not extend to very great distances, and are probably regulated by the abundance or scarcity of food. The time of the return of certain species to certain coasts is very confidently reckoned upon by the natives of the north and by seal-hunters.

Seal-hunting—or *fishing*, as it is often called—requires great patience and skill. Most of the seals, if not all, are gregarious, and one seems to be always placed on the watch, where danger is to be apprehended from bears or from hunters. They climb up through holes in the ice-fields of the polar seas, even when there is a height of several feet from the water, but it is difficult for the hunter to get between them and the hole. Nor is seal-hunting unattended with danger, an enraged S. being a formidable antagonist, at least to the inexperienced.

Seal-hunting is the great occupation of the Greenlanders, but it is also extensively prosecuted in other northern parts of the world; great numbers are taken on the coasts of Newfoundland and other northern parts of America; whale-fishers kill seals as they find opportunity; and vessels are fitted out expressly for the purpose, from the northern parts of Europe and of America.

SEALING-WAX. A composition of hard resinous materials used for receiving and retaining the impressions of seals. Simple as it may appear, its manufacture is one of great importance, and formerly was far more so than at present—the use of gummed envelopes having to a great extent superseded it. Common beeswax was first used in Great Britain and in Europe generally, being mixed with earthy materials to give it consistency. Nevertheless, it was difficult to preserve it, as a very small amount of heat softened it.

The Venetians, however, brought the Indian sealing-wax to Europe, and the Spaniards received it from the Venetians, and made it a very important branch of their commerce. The great value of the Indian wax consisted in the fact that it was made only of shell-lac, covered with vermilion or some other pigment, and this has been found superior to all other materials. In addition to the shell-lac and colouring material, there is always added to the wax made in Europe a portion of Venetian turpentine (see TURPENTINE), and of resin.

SEA-LION. See OTARY.

SEA-LION, in Heraldry, a monster consisting of the upper part of a lion combined with the tail of a fish.

SEAL ISLANDS, or LOBOS ISLANDS. See PERU.

SEALKOTE, a town in the Punjab, near the left bank of the Chenab, 65 miles north-north-east from Lahore. It contains about 20,000 inhabitants, and carries on the manufacture of paper. S. was formerly a military station, and at the period of the outbreak of the Indian mutiny, there was a rifle-practice dépôt here. All the European troops had been removed in July 1857 to repress disturbances that had broken out elsewhere, and on the 9th of that month the native troops fired on their officers. A considerable number of Europeans were killed, and the survivors suffered great privations until the sepoys, having plundered the station, started off in the direction of Delhi.

SEAL OF CONFESSION. See CONFESSION and CONFIDENTIALITY.

SEAMEN are technically those persons below the rank of officer, who are employed in navigating decked vessels on the high seas—men working on lakes and rivers being usually styled 'watermen.' Two opposite conditions are essential to the well-being of the vessel—first, the absolute subordination and perfect obedience of the crew to the master; and secondly, their protection against tyranny or caprice on his part. For this purpose the law of England is extremely minute in the rules laid down for both masters and seamen.

By an act of 1845, specially levelled against pimps and swindling agents, no person may hire seamen except the owner or master of a ship, and individuals licensed for that purpose by the Board of Trade. Under the Mercantile Marine Act of 1850, a written agreement must be made when a man is engaged, setting forth the nature and length of voyage, the capacity in which the man is to be employed, wages, fines, provisions, punishments, &c. If the ship be going abroad, this agreement must be attested before a shipping-master, who has a power of periodical inspection over the agreements of all seamen in vessels in his port. Any clause in the agreement would be inoperative which deprives the sailor of a lien upon his ship, or of other recovery for his wages, or of rights of salvage. In virtue of this agreement the seaman is bound to do his utmost in the service of the vessel; and consequently, if a master of a ship in distress promise his men extra pay for extraordinary exertions, the men cannot compel him to fulfil his promise.

In the event of disobedience or insubordination the master may administer correction, the law holding him responsible that such correction is reasonable. Desertion from the ship is punishable by imprisonment; and deserters may be apprehended on the information of the master without warrant. In case of open mutiny, the master may adopt the most stringent measures.

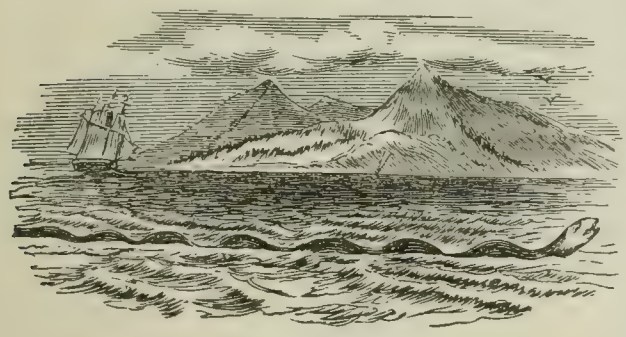
The mariners' wages are contingent on the success of the voyage; consequently, if the ship be lost or taken, the seamen lose their claim on the owners. It is a misdemeanour for the master to leave a sailor on shore in foreign parts, unless through the man's wrongful act.

SEA MOUSE (*Aphrodite*), a genus of dorsibranchiate annelida, of the family *Aphroditidæ*, to all of

Sea Mouse (*Aphrodite aculeata*).

which the popular name is extended. They are readily distinguished by two longitudinal ranges of broad membranous scales covering the back, under which are the gills in the form of little fleshy crests. The scales move up and down as the animal respires; and are concealed by a substance resembling tow or felt, which permits the access of water but excludes mud and sand. The head is furnished with tentacles; some have two eyes and some four. The body is edged with spines. Besides all this, its sides are covered with flexible bristles or silky hairs, which give to these creatures a wonderful beauty of colour, unsurpassed by that of humming-birds or the most brilliant gems. Each hair, even when viewed singly, and moved about in the sunshine, reflects all the hues of the rainbow. Yet sea-mice are generally to be found concealed under stones, and dwell amongst the mud at the bottom of the sea. Storms frequently throw them on the beach in great numbers. A very beautiful species, *A. aculeata*, of an oval form, about 6 or 8 inches long, and 2 or 3 broad, is the Common S. M. of the British coasts.

SEA PIKE (*Centropomus undecimalis*), a fish, which, notwithstanding its popular name, belongs to the perch family. Its form, however, is elongated like that of the pike. The body is compressed; there are two dorsal fins; the mouth is not very large; and the teeth are numerous, small, and equal. The colour is silvery-white, tinged with green on the back. It is found on the western coasts of tropical America. It attains a large size, and is a valuable fish. On the British coasts, the name S. P. is sometimes given to the Garfish.



SEA PINK. See THRIFT.

SEARCH OF ENCUMBRANCES means the inquiry made by a purchaser or mortgagee of lands as to the burdens and state of the title, in order to see whether his purchase or investment is safe. Owing to the want of any general system of registration of deeds affecting land in England, it is not possible by any search to find out with certainty all these burdens; nevertheless, there are some special registers which are usually included in such searches, such as judgment debts, bankruptcies, disentailing deeds, annuity deeds, &c. The search usually goes back for 60 years. In Scotland, where all the deeds affecting land rights are registered, it is easy to discover the exact state of the title and burdens on the land. The usual search is made only for 40 years. The registers are subdivided into various kinds—as the general and particular Register of Sasines, the Record of Abbreviates of Adjudications, Register of Inhibitions, &c. See RECORDS.

SEARCH-WARRANT is an authority granted to a constable by a justice of the peace to enter the premises of a person suspected of secreting stolen goods, in order to discover, and if found to seize the goods; and similar warrants are granted to discover property in respect of which other offences are committed. Before such a warrant can be issued, a credible witness must on oath prove a reasonable cause to suspect that the party proceeded against has the property in his possession or in his premises. The name of the person whose premises are to be searched must be correctly described in the warrant.

SEA-SERPENT. There are in the tropical and sub-tropical seas from the southern coasts of Asia to the South Sea Islands, numerous sea-serpents, which in so far as they are yet known, are all venomous, and belong to the family *Hydridæ* (q. v.). None of them, however, is known to exceed 5 feet or thereby in length, so that their existence cannot account for the stories which from time to time have been published of the appearance of a Great Sea-serpent, which, moreover, generally relate to the Atlantic Ocean, where none of the Hydridæ have yet been found. It is still doubtful whether or not the Great Sea-serpent ought to be reckoned among creatures merely fabulous or imaginary. Pontoppidan speaks of it in his *Natural History of Norway*, assigning to it a length of 600 feet, and describes it, not from personal observation, however, but from the testimony of others, as lying in the water in many folds, and appearing like many hogsheads floating in a line, at a considerable distance from each other. Such a creature is said to have

appeared more recently on the coast of Norway, in 1819, and to have been seen daily for a whole month, seeming to doze in the sunbeams; and again there is a story of its appearing in 1822, and another of its appearing in 1837, when it greatly alarmed some fishermen who thought that it followed their boat. Hans Egede mentions its appearance on the coast of Greenland in 1734. Mr M'Clean, the minister of a parish in the Hebrides, saw a sea monster in 1809, which, however, he supposed to be only 70 or 80 feet long, of serpent-like form; which was also seen, about the same time, by the crews of a number of fishing-boats, and caused them great alarm. In his description of this animal, he distinctly states that it seemed to move by 'undulation *up and down*,' which is not only contrary to all that is known of serpents, but from the structure of their vertebræ, impossible. (See SERPENTS.) Several instances have occurred of the supposed appearance of the Great Sea-serpent on the Atlantic coasts of North America. In June 1815, and in August 1817, it is said to have been frequently seen, in calm bright weather, near Gloucester, about 30 miles from Boston, on the surface of the water, like a number of buoys in a line, and sometimes moving very rapidly. Testimonies vary as to the length, from 80 feet to 250 yards. We hear again of the Sea-serpent as seen off Nahant, near Boston, in August 1819, in calm and serene weather, making curves 'perpendicular to the surface of the water,' and its eye 'brilliant and glistening.' A similar account is given of its appearance off Nahant in July 1833. In Silliman's *Journal of Science* for 1835 there is a notice of such an animal seen by the captain and crew of an American brig, on her passage from Boston to New Orleans, and also of a similar occurrence in lat. 34½°, and long. 48° W. Great interest was excited in 1848 by an account of a Great Sea-serpent seen in lat. 24° 44′ S., and long. 9° 20′ E., and therefore in the South Atlantic Ocean, near the Tropic of Capricorn, and not very far from

Sea-serpent.
(From Pontoppidan.)

the coast of Africa, by the officers and crew of her Majesty's frigate *Dædalus*. It was not, as in other cases, in bright and fine weather, but in dark and cloudy weather, and with a long ocean swell. The animal was swimming rapidly, and with its head and neck above water. Captain M'Quhae, in his Report to the Admiralty, describes it with confidence as 'an enormous serpent, with head and shoulders kept about 4 feet constantly above the surface of the sea;' and he adds: 'as nearly as we could approximate by comparing it with the length of what our maintopsail-yard would shew in the water, there was at the very least 60 feet of the animal *à fleur d'eau*, no portion of which was, to our perception, used in propelling it through the water, either by vertical or horizontal undulation. It passed rapidly, but so close under our lee-quarter, that had it been a man of my acquaintance, I should have easily recognised his features with the naked eye; and it did not, either in approaching the ship or after it had passed our wake, deviate in the slightest degree from its course to the south-west, which it held on at the pace of from 12 to 15 miles per hour, apparently on some determined purpose. The diameter of the serpent was about 15 or 16 inches behind the head, which was, without any doubt, that of a snake; and it was never, during the twenty minutes that it continued in sight of our glasses, once below the surface of the water; its colour a dark-brown, with yellowish-white about the throat. It had no fins, but something like the mane of a horse, or rather a bunch of sea-weed, washed about its back.' Regret has been very naturally expressed that Captain M'Quhae did not bestow a shot on it. Figures prepared from a sketch by him were published in the *Illustrated London News* of 28th October 1848. About the same time, the testimony of another witness, Lieutenant Drummond, appeared, and was found to differ in some important points from the account of the animal given by Captain M'Quhae, and the figures published with his approbation, particularly in ascribing a more elongated form to the head, in the mention of a back-fin, whereas Captain M'Quhae expressly says that no fins were seen; and in a lower estimate of the length of the portion of the animal visible. Lieutenant Drummond's words are: 'The appearance of its head, which, with the back fin, was the only portion of the animal visible, was long, pointed, and flattened at the top, perhaps 10 feet in length; the upper jaw projecting considerably; the fin was, perhaps, 20 feet in the rear of the head, and visible occasionally; the captain also asserted that he saw the tail, or another fin about the same distance behind it; the upper part of the head and shoulders appeared of a dark-brown colour, and beneath the under jaw a brownish-white. It pursued a steady and undeviating course, keeping its head horizontal with the water, and in rather a raised position, disappearing occasionally beneath a wave for a very brief interval, and not apparently for the purposes of respiration. It was going at the rate of perhaps from 12 to 14 miles an hour, and when nearest was perhaps 100 yards distant. In fact, it gave one quite the idea of a large snake or eel.' Lieutenant Drummond's account is the more worthy of regard, as it is derived from his log-book, and so gives the exact impressions of the hour, whilst Captain M'Quhae's was written from memory after his arrival in England. Into the discussion which arose concerning this case, it is out of our power to enter.

There is no reason to doubt the truthfulness of the statements made in any of these cases, although, in most of them, there is room for doubt as to the accuracy of observation. It has been suggested, and not without much appearance of probability, that the supposed sea-serpent might in some instances be a mere line of porpoises or such cetaceans, which often follow one another in lines. It has been thought that a line of floating sea-weed might account for the appearances presented. It has also been suggested that the creature seen from the *Dædalus* might be a sea-elephant or other large seal, swimming for its life, far from land. And Dr Owen has expressed much doubt as to the existence of a Great Sea-serpent on the ground that no bones or other remains of any such recent animal have occurred; and this negative evidence he regards as more than enough to counterbalance all the positive evidence yet adduced in favour of its existence. It is, however, to be remembered, that there are many fishes which inhabit the depths of the ocean, and seldom visit the shallower waters near the shores,

some of which are scarcely known except by single specimens; and the same thing is true as to Cetacea; so that it is very far from improbable that many species belonging to the ocean depths are still unknown to us. As to the Great Sea-serpent, if we should admit the general accuracy of the accounts given of it by those who supposed themselves to have seen it, there is no reason for concluding it to be a reptile; it might at least as easily be supposed to be a fish of elongated form, and, indeed, much more probably, as a reptile would need to come to the surface to breathe, which a fish would not. The first volume of the *Wernerian Society's Transactions* contains an account of an animal, 56 feet long, which was cast ashore on the island of Stronsa, one of the Orkneys, in 1808, and of which some of the vertebræ are preserved in the Museum of the University of Edinburgh, but which, unfortunately, did not come under the observation of any competent naturalist in its perfect state. On the high authority of Dr Owen, it is pronounced to have been a basking shark; but other men of science have expressed a different opinion.

SEA-SHORE, or land bordering on the sea, belongs partly to the crown, and the public have certain rights in relation thereto. The soil or property in the sea-shore is vested in the crown, and the limit on the land side is defined to be the medium line of high-water of all the tides in the course of the year, or the height of the medium tides in each quarter of a lunar revolution during the whole year. But though the crown is *prima facie* the owner of the sea-shore, the owner of the adjoining manor has sometimes a grant of it, and he proves this grant by ancient use—such as gathering sea-weed, &c. The public have a right to walk on that part of the shore vested in the crown, which holds it as a trustee for them. But the public have no right to trespass on the adjacent lands in order to get at the shore, so that it is only where a highway leads to the shore, or the public land from seaward, that the right can be made available. Thus it has been decided that the public have no legal right to trespass on the adjoining lands in order to get to the shore for purpose of bathing. The public have a right to fish on the sea-shore if they get legal access to it, and may take all floating fish, but not oysters or mussels which adhere to the rock, if the soil belongs to an individual. The public have no right to gather sea-weed or shells, though, as regards the latter, it is of so little consequence that nobody prevents them. Nor have fishermen a right to go on that part of the sea-shore which is private property to dig sand for ballast, or to dry their nets, or similar purposes, though in a few cases local customs permitting this have been held valid. In Scotland, the right to the sea-shore is also vested in the crown, but when a crown grant gives land bounded by the sea-shore, this is held to give to the grantee the fore-shore also.

SEA-SICKNESS is a variety of vomiting deserving of special notice. It is often preceded by premonitory symptoms, which appear almost immediately after a susceptible person is exposed to the motion of rolling water in a vessel or boat, and are as distressing as the vomiting itself. Amongst these symptoms may be mentioned vertigo and headache, with a peculiar feeling of sinking and distress about the pit of the stomach. Vomiting, however, in general, soon comes on, accompanied with convulsive heaving of the stomach, and such an indescribable feeling of prostration as to render the patient utterly regardless of what is going on around him, and almost indifferent to life. Moreover, a deadly pallor, a profuse cold sweat, and diarrhœa, are more or less commonly present. The susceptibility to this troublesome affection varies extremely in different persons. Some never suffer from it, others only on their first voyage, and others, again, in every voyage they undertake; with some it continues but a few hours, while others suffer almost continuously throughout a long voyage. In the great majority of cases, the sickness disappears in a few days, unless the weather be very boisterous. It almost always ceases on landing, although more or less giddiness may prevail for some hours, the patient when walking feeling as if the earth were rising up under his feet. Infants and aged persons are supposed to possess a comparative immunity from sea-sickness, while, as a general rule, women suffer more than men. According to Dr Althaus, persons with a strong heart and a slow pulse generally suffer little from sea-sickness; while irritable people, with a quick pulse and a tendency to palpitation, are more liable to be affected; and he thus accounts for different liability of different nations to this affection; 'for, as a rule, the French and Italians, being of a more irritable temper, suffer most from the disorder, the Germans less, and the English least.' ('On Sea-sickness as a form of Hyperæsthesia,' in *Proceedings of the Medico-Chirurgical Society*, vol. v. p. 23.)

The primary cause (or rather condition) of sea-sickness is the motion of the ship; and the *pitching* of a vessel, or alternate rising and falling of the bow and stern, is especially apt to produce it. It is less felt in large and heavily ballasted vessels, because the movements referred to are least perceptible in them. How this cause operates is a subject regarding which there has been much discussion; and without entering into the history of the views of different physicians on this subject, we may state that the most recent is that of Dr Chapman, who holds that the motions of the vessel cause the accumulation of an undue amount of 'blood in the nervous centres along the back, and especially in those segments of the spinal cord related to the stomach, and the muscles concerned in vomiting.' This condition is induced, as he maintains, in three different ways, viz., (1.) by the movements of the brain, which are much greater in a pitching vessel than on land; (2.) by the corresponding movements of the spinal cord; and (3.) by the excessive movements of the viscera within the abdominal and pelvic cavities. In one person the brain may be mainly responsible in causing that preternatural afflux of blood in the spinal cord, on which (according to Dr Chapman's hypothesis) sea-sickness depends; in another, the spinal cord may be the main agent; and in a third, the abdominal viscera; although each is always concurrent in some degree. Hence, the only scientific and really effective remedy for this disorder, must be one which has the power of lessening the amount of blood in the whole of the nervous centres along the back, and this can be done by lowering the temperature of the spinal region by the local application of ice. For a description of Dr Chapman's 'spinal ice-bags' (which may be obtained from any respectable surgical instrument-maker), and for the method of applying them, we must refer to his work *On Sea-sickness; its Nature and Treatment*, p. 37 (Lond. 1864). He gives the details of 17 cases in which the ice-bags were of greater or less benefit; in most of the cases, the result was perfectly successful. Besides Dr Chapman's evidence we have that of Captain White, commander of one of the Newhaven and Dieppe boats, who states that 'in ordinary weather it [Dr Chapman's remedy] is a success. I had some difficulty in persuading passengers to try it, but those who did were benefited.' Mr Bradley, surgeon in the

Cunard Service, in a letter to *The Lancet*, December 3, 1864, writes as follows: 'I have tried this remedy *in severe cases when other remedies have failed* (chloroform, iced champagne, effervescing draughts, fresh air, &c.), and have very generally found it do great good. In no case does it do harm, but in the great majority of instances it soothes the nervous irritability which so commonly accompanies severe sea-sickness, induces sleep, and consequently relieves exhaustion.' We are permitted to publish the following extract of a letter from Dr Hayle of Rochdale, to Dr Chapman, dated June 3, 1865: 'I recommended a patient about to cross the Atlantic, to try one of your ice-bags for sea-sickness. The result was most satisfactory. He was never sick when wearing the bag. Once he went without it, and then, and then only, was he sick. His friend, who had no ice-bag, was frequently sick.' As an ancillary remedy, the drinking of iced water, or the swallowing of small lumps of ice, may be recommended. Dr Chapman prefers the ice, which, 'brought in contact with the peripheral ends of the nerves of the stomach, will act on the same principle as it does when applied to the spinal region.'

Those who are susceptible to this distressing affection, and have not the opportunity of trying the ice-bags, may, at all events, diminish the severity of the vomiting by assuming, and as long as possible retaining, the horizontal position, as nearly as possible in the centre of the ship's movement, and keeping the eyes closed. The compression of the abdomen, by means of a broad tight belt, sometimes gives relief. A few drops of chloroform on a lump of white sugar will sometimes check the tendency to vomiting in persons who only suffer slightly. A little arrowroot, flavoured with brandy or sherry, is usually a kind of food that will most easily remain on the stomach, when the severity of the symptoms is abating. Dr Wood, one of the most eminent of the American physicians of the present day, asserts that he has 'found nothing under such circumstances so acceptable to the stomach as raw salt oysters.'

SEASIDE GRAPE (*Coccoloba uvifera*), a small tree, of the natural order *Polygoneæ*, a native of the West Indies. It grows on the sea-coasts; has orbicular, cordate, leathery, shining, entire leaves, and a pleasant, subacid, eatable fruit, somewhat resembling a currant, formed of the pulpy calyx investing a bony nut. The extract of the wood is extremely astringent, and is sometimes called JAMAICA KINO. The wood itself is heavy, hard, durable, and beautifully veined.

SEA SLUG. See HOLOTHURIA.

SEASONING, a term in Cookery for the materials used to add flavour to food. They are chiefly salt, the spices, and pot-herbs. Salt is the most important, for it not only increases the sapidity of most kinds of food, but also adds to their wholesomeness.

SEASONS. In the article EARTH, the motions of the earth on which the changes of the seasons ultimately depend, are explained. The chief cause of the greater heat of summer and cold of winter is that the rays of the sun fall more obliquely on the earth in the latter season than in the former. See CLIMATE. Another concurrent cause is the greater length of the day in summer, and of the night in winter. Within the tropics, the sun's rays have at no time so much obliquity as to make one part of the year very sensibly colder than another. There are therefore either no marked seasons, or they have other causes altogether, and are distinguished as the *Wet* and *Dry* seasons. This is explained in the article RAIN. But in all the temperate parts of the globe, the year is naturally divided into four seasons—*Spring*, *Summer*, *Autumn*, and *Winter*. In the arctic and antarctic regions, spring and autumn are very brief, and the natural division of the year is simply into summer and winter, the winter being long, and the summer short; and this is very much the case also in regions of the temperate zones lying near the arctic and antarctic circles. In subtropical regions, the distinction of four seasons is, in like manner, very imperfectly marked. This distinction is everywhere arbitrary as to the periods of the year included in each season, which really vary according to latitude, and partly according to the other causes which influence climate; the seasons passing one into another more or less gradually, and their commencement and close not being determined by precise astronomical or other phenomena. The greatest heat of summer is never reached till a considerable time after the summer solstice, when the sun's rays are most nearly vertical, and the day is longest; the greatest cold of winter is in like manner after the winter solstice, when the day is shortest, and the sun's rays are most oblique; the reason in the former case being, that as summer advances the earth itself becomes more heated by the continued action of the sun's rays; in the latter, that it retains a portion of the heat which it has imbibed during summer, just as the warmest part of the day is somewhat after midday, and the coldest part of the night is towards morning. The four seasons of temperate regions are distinguished by the phenomena of nature which characterise them, and which are of the greatest importance in relation to the wants and labours of man. But the renewal of vegetative activity in spring is not to be ascribed entirely to the increasing warmth of the sun's rays. Plants are so constituted that a period of rest is followed by new activity, and this new activity very generally begins in the fresh circulation of sap and enlargement of buds whilst the cold of winter still continues unabated, or before it has reached its greatest intensity. A similar remark may be made with regard to some of the phenomena of animal life, which may as well be said to herald the approach of spring as to attend its first days of genial weather.

SEBASTIAN, SAINT, a very celebrated martyr of the early church, whose memory is venerated in both branches of the church, east as well as west (although the scene of his martyrdom was the city of Rome), and whose story has formed one of the most popular themes of Christian artists from the earliest times. His history is contained in the so-called acts of his martyrdom, which, although partaking of the legendary tone, are regarded as authentic, not only by Baronius and the Bollandists, but also by Tillemont and others of the more stringently critical schools of ecclesiastical history. S., according to this narrative, was born at Narbonne and educated at Milan. Although a Christian, he entered the Roman army, without, however, revealing his religion, and with the view of being enabled, by his position, to assist and protect the Christians in the persecution. In this way he supported and comforted many of the martyrs in Rome; and he even converted Nicostratus, the keeper of the prison in which the martyrs were confined, and his wife, Zoe, to whom he miraculously restored the use of her speech, after she had been dumb for six years. Still unrecognised as a Christian, S. rose to high favour under Diocletian, while at the same time the grateful pontiff, Caius, named him

'Defender of the Church.' At length came the time for his open profession of his faith. Diocletian used every effort to induce him to renounce the Christian creed, but in vain; and in the end he was condemned to be put to death by a troop of Mauritanian archers, who transfixed him with numberless arrows, and left him as dead. But a Christian lady, Irene, finding that life was not extinct, had the body removed to her house, where life was restored; and although the Christian community desired to conceal his recovery, S. again appeared in public before the emperor, to profess his faith in Christianity. Diocletian condemned him to be beaten to death with clubs in the amphitheatre; and his body was flung into one of the sewers of the city, in which it was discovered, according to the Acts of Martyrdom, by means of an apparition, and carried by a Christian lady, Lucina, to the catacomb, which is still called by his name. The date of his martyrdom was January 20, 288. By the Greeks the feast is held on the 20th December. The festival was celebrated with great solemnity in Milan as early as the time of St Ambrose; and it was observed in the African Church in the 4th century. There is another saint of the same name, who is said to have suffered martyrdom in Armenia.

SEBASTIANI, FRANÇOIS-HORACE-BASTION, marshal of France, was born November 10, 1772, at Porta d'Ampugnano, a village near Bastia, in Corsica. He was the son of a tailor, but his extreme vanity led him to declare himself of noble descent and a distant relative of the Bonapartes. He entered the army as a sub-lieutenant of infantry, August 27, 1789. His rise, due to his bravery in the field, was no doubt somewhat aided by his splendid physique, graceful manner, and facile diction. He became *chef-d'escadron* in 1797, and brigadier in 1799, and was one of Napoleon's most devoted partisans. He fought at Marengo, executed some important diplomatic service in Turkey in 1802—1803, after which he became general of brigade (August 1803), and was wounded at Austerlitz. On May 2, 1806, he was again deputed to Turkey, this time to break the alliance of the Porte with Russia and England; and before he had been seven months at Constantinople, his mission had obtained complete success, and war was declared. The English fleet forced a passage through the Dardanelles, and cast anchor before Constantinople, their presence causing such terror among the sultan's ministers that a total reversal of foreign policy was imminent, but S., coming to the rescue, revived with his seducing eloquence their failing resolution, and assuming an authoritative superintendence of the preparations for defending the coast, put the batteries in a state fit for action. In five days, he had the coast batteries manned with 600 guns, 100 small gunboats afloat, a line of vessels laid along shore, each with a broadside ready to be discharged on the English fleet, which at last gallantly ran the gantlet, losing two ships and 700 men. But the death of the sultan, and the treaty of Tilsit, put an end to the French intrigues in Turkey, and S. was recalled June 1807, and decorated with the grand cordon of the Legion of Honour. He subsequently commanded the fourth corps-d'armée in Spain. He distinguished himself in the Russian campaign of 1812, and at Leipzig. On the exile of Napoleon to Elba, he gave in his adherence to the Bourbon government, but joined his old master on his return. After the revolution of 1830, he held for brief periods the portfolios of naval (1830) and foreign affairs, and the embassies to Naples (April 1833) and London (January 1835); but was more distinguished for his elegance, and graceful demeanour in the Parisian salons, than as a politician or administrator. He died at Paris, July 20, 1851.

SEBASTIANI'STAS, the name given in Portugal and Brazil to persons who believe in the future return to earth of the king Dom Sebastian, who fell in the battle of Alcazarquebir, 1578 A.D., while leading on his army against the Moors. This belief has continued to be entertained by many in Portugal; but the S. are said to be now most numerous in Brazil. On the return of Dom Sebastian, they expect Brazil to enjoy the most perfect prosperity and happiness.

SEBASTO'POL, or, as it is sometimes written, in accordance with modern Greek pronunciation, SEVASTOPOL (*Sebastopolis*, the 'august city'), a Russian seaport, fortress, and arsenal in the Crimea, in the government of Taurida. It is situated near the south-west extremity of the Crimea, on the southern side of the magnificent harbour or roadstead of S., one of the finest natural harbours in the world. This harbour is an inlet of the Black Sea, stretching inland for about four and a half miles from west to east, about half a mile wide at the entrance, but immediately opening out to the width of a mile, with an average width of about half a mile up to the eastern end. It is sheltered on the north and south by lofty limestone ridges shutting it completely in, with a depth of water varying from 3 to 11 fathoms, and sufficient in several places to allow ships of the largest size to lie close to the shore. At the eastern end, under the heights of Inkermann, the river Tchernaya enters the harbour through low marshy ground. The South Bay, or Dockyard Harbour as it is also called, extending about one and a half miles from north to south, forms the harbour proper of S.; and between it and Quarantine Bay, occupying rather more than half the peninsula thus formed, is built the chief portion of the town of S., on ground sloping irregularly upwards. The town, previous to its destruction in the siege of 1854—1855, was well and substantially built of stone, with lines of streets running from north to south, and smaller ones intersecting them at right angles, containing several handsome public edifices. The docks, constructed for the Russian government by Colonel Upton, an English civil engineer, were among the most important works at S.; the dock basin, docks, and quays were formed in the most substantial way, being partly cut in the solid rock, and lined with cement, partly built of limestone and granite. From the Dockyard Creek, ships were admitted into the Dock Basin by means of three locks, the bottom of the docks being above the sea-level, and the basin was supplied with water by a canal some 12 miles in length from the Tchernaya above Inkermann—itself a work of no inconsiderable magnitude. For the defence of town and harbour from attack by sea, several forts were erected. These forts were works of immense strength, built of limestone faced with granite, on which artillery was found to make but little impression; they mounted a very large number of guns, and by their cross-fire completely protected every spot accessible to a hostile fleet. On the land side, with the exception of a slight loopholed wall extending partially round the western side, the town, previous to the siege, was entirely undefended; but the earthworks and fortifications then successively extemporised by the genius of General Todleben, which for so many months kept the armies of France and England at bay, and of which the Malakoff and the Redan were the most formidable, are now of historic fame.

The siege of S. by the allied English and French armies will rank among the most famous sieges in

history; it lasted for 11 months, from October 1854 to September 1855; the place sustained repeated bombardments, the first of which took place October 17, 1854; and the capture of the Malakoff and Redan, on September 8, 1855, at length forced the Russians to evacuate it, and retire to the north side. The town had been completely ruined; the docks and forts (such as were still standing) were afterwards blown up by French and English engineers. By the treaty of Paris (March 1856), the naval and military works are not to be restored. Before the siege, the population of S., including the soldiers and marines forming the garrison, amounted to about 40,000. Since that time the town has been partially rebuilt and reinhabited, but the population in 1866 was only 10,537. S. was intended to be the station of the Russian Black Sea fleet, and as such to form a standing menace to Turkey; during the siege, the fleet was almost entirely destroyed, many of the ships having been sunk by the Russians across the entrance of the harbour by way of defence. The great disadvantage of S. as a naval station arises from the ravages of the *Teredo navalis*, which soon render wooden vessels unseaworthy. S. was founded on the site of a small Tartar village called *Akhtiar*, immediately after the Russian conquest of the Crimea in 1783, under the orders of the Empress Catharine II. The promontory on which S. stands is a spot of considerable classical and historical interest. Here, perhaps on the site now occupied by the Greek convent of St George, west of Balaclava, stood the temple of the Tauric Artemis, in which, according to the legend, Iphigenia, daughter of Agamemnon, was priestess. In later times, the promontory was colonised by Greeks from Heraclea, in Asia Minor, and became known as the Heracleotic Chersonese. Two cities, successively built a few miles apart on the sea-coast to the west of S., have left remains existing to the present day. In after times, the Chersonesus fell into the power of the Genoese, who established their headquarters at Balaclava, where the remains of the 'Genoese castles' on the heights still bear witness to their rule. See *History of the Russian War* (W. and R. Chambers).

SEBE'NICO, a small port on the coast of Dalmatia, 42 miles south-east of Zara. It is built on a steep slope, and rises in terraces, and was formerly defended by walls and towers. Its cathedral, a fine edifice with a bold dome, was built 1443—1536. Its excellent harbour is defended by several forts. Pop. 14,238.

SEBE'STEN, SEBESTAN, SEPISTAN, or S. PLUM, the fruit of the *Cordia Myxa*, a tree of the natural order *Cordiaceæ*, a native of the East Indies. The tree has ovate leaves, and an egg-shaped fruit, which is succulent, mucilaginous, and emollient, with some astringency, and was formerly an article of the European Materia Medica, being employed for the preparation of a lenitive electuary and of a pectoral medicine. It is believed to be the *Persea* of Dioscorides. It has a sweetish taste, and is eaten by the natives of the Northern Circars of India, where it grows.

SECLU'SION (of the Insane). This term has recently been narrowed so as to apply to the removal of the violent insane from the ordinary wards and fellowship of an asylum to an airing court, gallery, or room so situated and furnished that its solitary occupant can neither injure himself, nor injure nor disturb others. Since the abolition of physical restraint by chains and strait-jackets, seclusion has become a favoured and useful mode of repression and treatment. That it should be resorted to exclusively as a remedial agent, and by the medical attendant, is now received as an axiom. In 1854, the Commissioners in Lunacy in England ascertained, by circular, the opinions of almost all those intrusted with the care of the insane in that country, as to the employment of such means of cure; when it appeared that it was generally considered beneficial, if used for short periods and during paroxysms of epileptic and violent mania. Even when not absolutely required for the tranquillisation of the individual, seclusion may become expedient in order to secure the quiet, comfort, or safety of the patients with whom he is associated. That such an instrument may be abused and adopted from the parsimony, timidity, or ignorance of those around, is obvious. One of the lunatics liberated by Pinel, in 1792, had been incarcerated or *secluded* in his dark cell for forty years; and occasionally even now the duration of the isolation may be unduly prolonged even under medical sanction; but the instances of gross and cruel seclusion in garrets and cellars, and outhouses, are now chiefly to be found in private families, and where, as in the 'Flushing case,' no better course is known to be practicable.—*Eighth Report of Commissioners in Lunacy to Lord Chancellor*, App. C, p. 123; Bucknill and Tuke, *Psychological Medicine*, p. 562; Browne, *What Asylums Were, Are, and Ought to be*, p. 137.

SECOND (for the derivation of which see SCRUPLE) is the sixtieth part of a minute, whether of time or of angular magnitude. See MINUTE. In old treatises we find seconds distinguished as *minutæ secundæ*, from minutes, or *minutæ primæ*. The sixtieth part of a second was called a third, but instead of this and succeeding subdivisions, decimal fractions of seconds are now employed.

SE'CONDARY, in Geology, is the designation given to that large section of the fossiliferous strata which includes the Triassic, Oolitic, and Cretaceous rocks. It is synonymous with Mesozoic. The strata grouped under this title are separated from the inferior and superior deposits more by their organic contents than their petrological structure, and this separation is more evident between them and the older rocks, than between them and the newer; and yet recent discoveries have shewn that the St Cassian Beds form a connecting link between the Permian and Triassic epochs. They contain a series of fossils which are partly Palæozoic and partly Mesozoic in their facies.

The appearance of the great types of all subsequent organisms in the Secondary rocks, has suggested the grouping of the fossiliferous strata in respect of their fossils into only two great divisions —viz., the Palæozoic and the Neozoic—this last term including the Secondary and Tertiary periods.

SECONDING is a temporary retirement to which officers of Royal Artillery and Royal Engineers are subjected when they accept civil employment under the crown. After six months of such employment the officer is seconded, by which he loses military pay, but retains his rank, seniority, and promotion in his corps. After being seconded for ten years, he must elect to return to military duty or to retire altogether.

SECOND SIGHT, a superstition or belief once common in the Scottish Highlands and Isles, where it was known by the Gaelic appellation *Taisch*, signifying a spectral or shadowy appearance. Certain persons, called seers or wizards, were supposed to possess a supernatural gift, by which they

involuntarily foresaw future events, and perceived distant objects as if they were present:

> As the sun,
> Ere it is risen, sometimes paints its image
> In the atmosphere, so often do the spirits
> Of great events stride on before the events,
> And in to-day already walks to-morrow.
> WALLENSTEIN.

This is to depict the lofty and poetical view of the subject, as illustrated in classic fable and early history. The Highland seer, however, was chiefly conversant with the scenes and occurrences of ordinary life. 'A man on a journey far from home falls from a horse; another who is perhaps at work about the house, sees him bleeding on the ground, commonly with a landscape of the place where the accident befalls him. Another seer, driving home his cattle, or wandering in idleness, or musing in the sunshine, is suddenly surprised by the appearance of a bridal ceremony or funeral procession, and counts the mourners or attendants, of whom, if he knows them, he relates the names, if he knows them not he can describe the dresses. Things distant are seen at the instant when they happen' (Johnson's *Journey to the Hebrides*). With respect to things future, Johnson thought there was no rule for determining the time between the sight and the event; but Martin, whose account of the Western Islands was first published in 1703, furnishes data of this kind in his classification of the visions. If an object was seen early in the morning, the event would be accomplished a few hours afterwards; if at noon, the same day; and if at night, the accomplishment would take place weeks, months, and sometimes years afterwards, according to the time of night the vision was beheld. The appearance of a shroud was an infallible prognostic of death, and the nearness or remoteness of the event was judged by the amount of the body that was covered by the ghastly sheet; if it was not seen above the middle, a delay of a twelvemonth might be hoped for, but if it ascended high towards the head, the mortal hour was close at hand. 'The vision makes such a lively impression upon the seers,' says Martin, 'that they neither see nor think of anything else except the vision, as long as it continues; the eyelids of the seer are erected, and the eyes continue staring until the object vanish.' The power of the seer was involuntary and painful—it was no source of gain. The gradation of symbolical appearances we have mentioned, strikes the imagination and gives something like a system to the supernatural phenomena. But if we turn to the cases described by the historians of the second sight, we do not find such regular order and exactness. The evidence is vague and confused, and the incidents are often of the most trivial character. The revelations, indeed, were commonly made to poor illiterate men, predisposed from the very nature of the country—wild, dreary, and remote—and from their half-idle, solitary life, to melancholy and superstition. These causes must have led very early to belief in the second sight. We find it colouring portions of the history of Wallace and Bruce, and associated with the tragic fate of the accomplished James I. of Scotland. A Scottish seer is said to have foretold the unhappy career of Charles I., and another the violent death of Villiers, Duke of Buckingham. In 1652, a Scottish lawyer, Sir George Mackenzie, afterwards Lord Tarbat, when driven to the Highlands by fear of the government of Cromwell, engaged himself in making inquiries concerning this supposed supernatural faculty, and wrote a minute account of its manifestations addressed to the celebrated Robert Boyle, which, with other relations on the same subject, is published in the correspondence of Samuel Pepys. Next came Martin's copious description; then a Highland minister, the Rev. John Fraser of Tyree, collected *Authentic Instances*, which were printed in 1707; and in 1763, appeared the ambitious treatise of *Theophilus Insulanus*, or Macleod of Hamir, which contained the narratives of Fraser, of Aubrey the English antiquary, and other authorities, with the addition of a great number of cases—nearly a hundred—gathered by himself from various sources, and also numerous letters from Highland ministers. This work exhausted the subject, but the wretched vanity, credulity, and weakness of Theophilus covered it with ridicule. A fresh revival took place after the memorable *Journey to the Hebrides* by Dr Johnson, whose work was published in 1775. The second sight was sure to interest a melancholy, meditative 'rambler' like Johnson. He had read of it in his youth in Martin's History. He was naturally superstitious. He had a stout courageous heart and strong nerves in all mundane matters and positions, but he had a morbid fear of death, and an almost childish eagerness to pierce the darkness of futurity, and to believe in the possibility of messages from the other world. Johnson anxiously questioned the clergy and others respecting the supernatural communications made to the seers, and would gladly have believed them real. The evidence, however, was not complete or invincible; and with that love of truth, which was one of the strongest virtues of the sage of Bolt Court, he confessed that he never could 'advance his curiosity to conviction, but came away at last only willing to believe.' On one occasion we find Johnson enunciating the true doctrine in such cases. He observed, as Boswell reports, that 'we could have no certainty of the truth of supernatural appearances unless something was told us which we could not know by ordinary means, or something done which could not be done but by supernatural power; that Pharaoh, in reason and justice, required such evidence from Moses; nay, that our Saviour said: "If I had not done among them the works which none other man did, they had not had sin."' Undoubtedly works or facts, not merely appearances, are required for conviction. Spectral sights may be caused by dreams or disease (see APPARITIONS), by accidental optical illusions, or by the workings of a vivid imagination. It seems degrading to the idea of divine power to suppose that special miracles were wrought to announce the marriage or death of a Highland peasant, the wreck of a boat, or the arrival of a stranger in a remote island of the Hebrides. Ignorance is a great ally of superstition, as solitude is of gloomy egotism and melancholy; and since education has penetrated into the Highlands and Isles, and intercourse with other parts of the kingdom has been facilitated by increasing trade and improved means of communication—to say nothing of the effects of that passion for Highland scenery and sport which every year takes crowds of visitors to the country—the belief in second sight, as in astrology and witchcraft, has almost wholly disappeared from the land. It never had the cruel, hard, and revolting features of witchcraft—formerly prevalent in the Lowlands when scarcely known in the Hebrides—and it still seems picturesque enough to serve for the purposes of poetry and romance.

SECRET (Lat. *secreta*, i. e., *oratio*, the secret prayer), one of the prayers of the Mass (q. v.), of the same general form with the 'Collect,' but recited by the priest in so low a voice as not to be heard by the people, whence the name *secreta* is derived. It follows immediately after the oblation of the Eucharistic bread and wine. This use of silent prayer in

the public service is one of the subjects of controversy between Catholics and Protestants.

SECRET, DISCIPLINE OF THE (Lat. *Arcani Disciplina*), a discipline of the early church, founded upon the words of Christ, 'Give not that which is holy to dogs,' Matt. vii. 6, in virtue of which Christians fully initiated in the doctrine and practice of the church withheld from pagans and catechumens in the preparatory stage the knowledge of certain doctrines, and the liberty of presence at certain rites connected with the most solemn mysteries of the Christian religion. This practice originated in the obloquy which was drawn upon the doctrines of the church from the false and monstrous conceptions of these doctrines which were circulated among pagans. Against these calumnious misconceptions the earliest of the so-called 'Apologies' are addressed; and it seems certain that at the time at which Justin wrote his first Apology, the middle of the 2d c., no objection existed against speaking openly of the mystery of the Eucharist.—(See *Justini Apol.*, i. 66). Very soon after this, however, the 'Secret' is clearly traceable. The first reason for its adoption was that assigned above—namely, to guard the more sacred and mysterious doctrines from popular misconception and blasphemy among the pagans. This precaution of concealment was extended to catechumens, partly in order to avoid shocking too suddenly their half-formed convictions by the more startling improbabilities of Christian belief; partly also, no doubt, to guard against the danger of the betrayal of these mysterious doctrines to pagan spies approaching in the false garb of catechumens. The Discipline of the Secret appears in several forms—(1.) Both unbelievers and catechumens were removed from the church at the commencement of that portion of the liturgy which specially relates to the celebration of the Eucharist—the so-called *Missa Fidelium*. See MASS. (2.) The lectures addressed by the presiding teacher to the great body of the catechumens in general were confined to the general doctrines of Christianity. The more mysterious doctrines, those which regarded the sacraments of Baptism and the Eucharist, called 'Mystagogic,' were only communicated at the close, and to those only who had undergone the preliminary probation. (3.) The Eucharist, if referred to at all in the presence of the uninitiated, was spoken of in words so conceived as to conceal its nature. Many curious examples of this concealment might be cited. Origen, alluding to the Eucharist (Hom. 8, in Exod. 4), says merely: 'The initiated know what I mean.' When Chrysostom was writing to Pope Innocent I. an account of a tumult in the church at Constantinople, in which the sacred cup was overset, and the consecrated elements spilled, he says, without reserve, 'The blood of Christ was spilled.' But Palladius, the deacon, in his Life of Chrysostom, which was designed for the pagans as well as for the Christians, takes the precaution to use the words 'The symbols which are known to the faithful.' Still more curiously, Epiphanius, in citing the well-known words of the Eucharistic formula, 'This is my body,' suppresses the word under which the mysterious idea is contained, and writes, 'This is my *that thing*.' *Touto mou esti tode*. A very curious example of this amphibological language regarding the Eucharist will be seen in a Greek inscription discovered some years since at Autun, in France.—(See *Edin. Rev.*, July, 1864).

There is some uncertainty as to the period during which this discipline lasted in the church. It commenced most probably in the time of Justin, as his contemporary, the heretic Marcion, is known to have protested against it as an innovation (Neander's *Kirchen-geschichte*, i. 540). It is even thought not impossible by some that Justin's mode of writing was an exceptional one, and that the Secret may have been in use before his time. On the other hand, it is certain that it outlived the period out of the condition of which it arose, and was maintained long after the ages of persecution. The traces of it had not entirely disappeared in the 6th century.—(See Schelstrate, *Diss. de Discip. Arcani*, 1685; Scholliner, *Diss. de Discip. Arcani*, 1756; and on the Protestant side, Tenzel, *De Discip. Arcani* (in reply to Schelstrate); Rothe, *De Disc. Arcani*, Heidelberg, 1831.)

SE'CRETARY, SECRETARY FALCON, SECRETARY BIRD, or SERPENT-EATER (*Gypogeranus*), a genus of birds of prey, which has been variously placed by naturalists among the *Falconidæ* and the *Vulturidæ*, and has been also constituted into a distinct family, *Gypogeranidæ*. The legs are very long, as in the *Grallæ*, to which, however, there is no other resemblance. The *tibiæ* are completely feathered, but the *tarsi* and toes are destitute of feathers. The tarsi are covered in front with long, large scales. The toes are armed with sharp claws; but they are short, and the feet are not formed for grasping. The hind-toe is very short. The neck is much longer, and the whole form of the bird more slender than in the Falconidæ. The wings are long, and armed with a blunt spur at the shoulder. The tail is very long. The best-known species is an inhabitant of the arid plains of South Africa. It is about three feet in length; the plumage bluish-gray. It has an occipital crest of feathers without barbs at the base, which can be raised or depressed at pleasure, and the name Secretary was given to it by the colonists at the Cape of Good Hope from their fancied resemblance to pens stuck behind the ear. It feeds chiefly on reptiles of all kinds, which it devours in great numbers, and is so highly valued on account

Secretary Bird (*Serpentarius secretarius*).

of the constant war which it wages against serpents, that a fine is inflicted in the Cape Colony for shooting it. It fearlessly attacks the most venomous serpents, stunning them with blows of its wing, also seizing and carrying them into the air to such a height that they are killed by the fall. It uses its feet also to overpower its prey, striking violent blows with them. Small serpents are swallowed entire; the larger ones are torn to pieces. The S. is most frequently seen in pairs, or solitary. It is tamed as a protector of poultry-yards; but if not sufficiently fed, is apt to help itself to a chicken

or duckling. An attempt has been made to introduce this bird into Martinique, in order to reduce the number of venomous serpents in that island.

SECRETARY OF THE NAVY is an officer of the executive department and member of the cabinet, selected by the President, and having charge of the naval establishment of the United States, under the general direction of the executive. All instructions to commanders of squadrons and commanders of vessels, orders to officers, appointments of commissioned and warrant officers, &c., emanate from his office. He receives a salary of $8000 a year. The British Secretary of the Navy is the constitutional title of the parliamentary secretary to the Board of Admiralty. The post is conferred on a naval officer of high rank sitting in the House of Commons. He receives £2000 a year. A permanent secretary receives £1500 a year, who is responsible for the discipline of the admiralty office. S. Pepys, author of *Pepys' Diary*, long held the latter office.

SECRETARY OF WAR is an officer of the executive department and member of the cabinet, selected by the President, and having charge of all duties connected with the army of the United States, fortifications, &c., issues of commissions, movement of troops, payment, commissary, &c., and engineering. He receives a salary of $8000 a year. The British Secretary of War was formerly a high officer of the British ministry, having control of the financial arrangements of the army and being the responsible medium for parliamentary supervision in military affairs. The formation of a war-office proper took place about 1620, the Secretary of State having previously performed its duties. It was, however, limited to financial authority, neither the commander-in-chief nor the master-general of the ordnance being subject to it. During the Russian war the evils of this divided authority led to the creation of a Secretary of State for War, to control all the military departments. The Secretaryship-at-War was merged in the superior office in 1855, and abolished by act of parliament in 1863.

SECRETARY OF EMBASSY or of LEGATION, the principal of the persons belonging to the suite of an ambassador or envoy. Secretaries of Embassy or Legation hold their commission immediately from the sovereign, who nominates them in general only to ministers of the first and second rank. They are therefore considered a species of public minister; and independently of their attachment to an ambassador's suite, they enjoy in their own name all the privileges and protections of the diplomatic character. They are generally presented in person to the foreign sovereign at whose court they are accredited. The functions of a secretary of embassy or legation consist principally in assisting the chief in the business of the embassy. Moser (*Versuch Th.* iii. p. 94) says: 'An ambassador is often only like the hands of a watch, while his secretary resembles the works.' Secretaries of embassy and legation occupy the post of ambassadors and envoys during the absence of their ministers. A secretary of embassy or legation must not be confounded with the private secretary of an ambassador appointed and paid by him, who has none of the privileges and immunities above-mentioned.

SECRETARY OF STATE, an ancient and important office in the government of England. The oldest record of its existence is in the reign of Henry III., when John Maunsell is described as 'secretarius noster.' Prior to the Restoration, the holder of this office was generally styled the 'king's chief' or 'principal secretary;' he had the custody of the king's signet, and discharged his duties with the assistance of four clerks. Two secretaries are said to have been first appointed towards the close of the reign of Henry VIII. The office, always one of influence, gradually grew in importance. On the Union of 1707, Anne added a third secretary of state for Scotland, which office, however, was soon done away with. In the reign of George III. there were at first but two secretaries; for a time there was a third for America, but his office was abolished by statute in 1782. While the secretaries were two in number, both equally directed home affairs; to the one were committed the foreign affairs of the northern, to the other of the southern department. Irish affairs belonged to the province of the elder secretary.

There are now five principal secretaries of state, who are respectively appointed for home affairs, foreign affairs, war, the colonies, and India. They are all appointed by the sovereign by the mere delivery of the seals of office, without patent, and are always members of the Privy Council and of the Cabinet. Though each has his own department, he is considered capable of discharging the duties of the others; a member of the House of Commons, if removed from one secretaryship to another, does not thereby vacate his seat.

The Secretary of State for the Home Department has the charge of the maintenance of the internal peace of the United Kingdom, the security of the laws, and the administration of justice, so far as the royal prerogative is involved in it. He directs the disposal and employment of the regular troops at home, and provides for the suppression of riots. The militia, yeomanry, and volunteers are entirely under his control. He has the ultimate supervision of all that relates to prisons and criminals; and numerous statutory powers have been given him regarding police, sanitary matters, the regulation of labour, &c. All patents, licences, dispensations, charters of incorporation, commissions of the peace and of inquiry, pass through his office. He recommends persons to the Sovereign for civil knighthood, and is empowered to grant certificates of Naturalisation (q. v.) to foreigners. He is the organ of communication between the cabinet and the viceregal government of Ireland, for which he is responsible, and is informed of and advises all the graver measures adopted in that country. His patronage is very considerable, including the nomination to a large number of judicial offices. Among the powers of the Secretary of State is that of committing persons on suspicion of treason, a function which, though its legality has been called in question, has been often exercised.

The Secretary of State for Foreign Affairs is the responsible adviser of the crown in all communications between the government and foreign powers. He negotiates treaties, either directly with the foreign ministers resident in the country, or through the British ministers abroad. It is his duty to inquire into the complaints of British subjects residing in foreign countries, to afford them protection, and to demand redress for their grievances. The Foreign Secretary recommends to the Sovereign all ambassadors, ministers, and consuls to represent Great Britain abroad. He grants Passports (q. v.) to British subjects and naturalised foreigners.

The Secretary for the Colonial Department has the supervision of the laws and customs of the colonies, watches over their interests, directs their government, apportions the troops necessary for their defence or police, appoints the governors of the colonies, and sanctions or disallows the measures of the colonial governments, rarely, however, prescribing measures for their adoption.

Each of these four secretaries of state is assisted by two under secretaries of state nominated by

himself—one usually permanent, while the other is dependent on the administration in power.

The Secretary of State for India, whose office dates from the abolition, in 1858, of the double government of India by the Court of East India Directors and Board of Control, has the same control over the government of India which was formerly exercised by these bodies, and countersigns all warrants and orders under the sign-manual relating to India. He is assisted by an under-secretary, who is also a member of the legislature, and loses office with the cabinet, and by a permanent under-secretary and a council. Every order sent to India must be signed by the secretary, and all dispatches from governments and presidencies in India must be addressed to him. The Chief Secretary for Ireland resides in Dublin and is secretary of the Lord Lieutenant.

The Department of State for the United States was established July 27, 1789, and was originally styled the Department of Foreign Affairs.

The Secretary of State of the United States is an officer of the executive department and member of the cabinet, selected by the President, and is charged with all duties relative to correspondence, commissions, or instructions to foreign ministers, consuls, &c. He receives and preserves the enrolled acts of Congress, and has charge of their publication. He is custodian of the seal of the United States, and it is his duty to affix the seal to all civil communications and other instruments and acts whenever he has special warrant of the President therefor. The secretary receives a salary of $8000 a year, and the two assistant secretaries each receive $3500 a year.

SECRETION is the term employed in Physiology to designate the process of *separation* of those matters from the nutritious fluids of the body which are destined not to be directly applied to the nutrition and renovation of its organised fabric, but (1.) to be either at once removed as injurious to its welfare, or (2.) to be employed for some ulterior purpose in the chemical or physical processes of the economy itself, or to exert some kind of action upon other beings. For this definition of secretion considered as a process we are indebted to Dr Carpenter; but the reader must bear in mind that the term is also very commonly used in another sense—namely, to designate the *products* which are thus secreted. In this latter sense, it is customary to speak of the biliary, urinary, or cutaneous secretion, when the bile, urine, and sweat are indicated.

Although it is impossible to divide with strictness the secreted products (as many physiologists have attempted to do) into the *excrementitious* and the *recrementitious*—that is to say, into (1.) those which have no further function to discharge in the animal body, and which, if not excreted, would act as poisons, and (2.) those which are subservient to further uses in the system—yet we may group them according to the preponderance of their excrementitious or recrementitious character. Dr Carpenter approves of this mode of arrangement, and proposes that those secretory processes should be arranged in the first division in which the depuration of the blood is obviously the chief end, while those should be classed under the second in which the ulterior purpose of the separated fluid would seem to be the principal occasion of its production; and he further suggests a subdivision of this second group, according as this ulterior purpose is connected with the operations of the economy itself, as in the case of the tears, the saliva, the gastric juice, &c., or is destined to act on some other organism, as is the case with the secretion of the testes, the milk, &c. The organs which yield the various secretions are termed Glands (q. v.); but neither the form nor the internal arrangement of the parts of a gland have any essential connection with the nature of its product; the true process of secretion, under whatever form it may present itself, being always performed by the intervention of Cells (q. v.). For a notice of the mode in which the cells are arranged in various glandular structures, the reader is referred to the articles GLAND, LIVER, KIDNEY, MUCOUS MEMBRANE, &c.

We shall now briefly notice the causes which render the due performance of the functions of secretion essential to the well-being of every animal. 1. Nearly all the solids and fluids of the body are liable to continuous decomposition and decay in consequence of their peculiar chemical composition. There is an obvious necessity that the products of incipient decomposition should be carried off and replaced by newly-organised matter. 2. The exercise of the various animal functions is essentially destructive to the structures by which they are accomplished; every operation of the muscular or nervous system appearing to require, as a necessary condition, a disintegration or breaking up of a certain portion of their tissues, probably by an act of oxidation. Hence, for the due preservation of health, the disintegrated or effete matters must be removed, and their place supplied. 3. When more food is taken than the wants of the system require, all that is not appropriated to the reparation of the waste, or to the increase in the weight of the body, must be thrown off by the excretory organs without ever having become converted into organic tissue. If this excess were not speedily removed by the excretory organs, the current of the blood would speedily become poisoned.

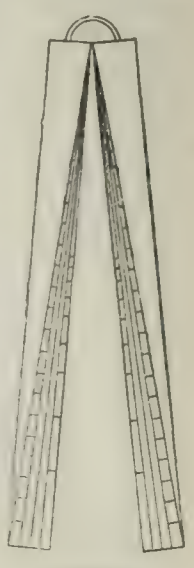
The following may be regarded as a tolerably complete list of the substances which are produced within the organisms of man and the lower animals by the disintegration of its various tissues, and which are met with in one or other of the products of secretion: 1. Products of secreting processes, including *a*, the biliary acids and the products of their disintegration; *b*, the pigments of the bile; *c*, pigments allied to those of the bile and blood, viz., hæmatoidin and melanin; *d*, cholesterin and its allies; *e*, the sugars and allied bodies. 2. Products of the actual regressive metamorphosis of tissues—*a*, nitrogenous amide-like bodies, such as leucine, tyrosine, creatine, creatinine, allantoin, cystin, guanine, sarcine, xanthin, and urea; *b*, nitrogenous acids, as hippuric, uric, and cynuric acids; *c*, indifferent nitrogenous bodies, such as the pigments occurring in the urine; and excretine; and *d*, non-nitrogenous acids, as acetic, benzoic, butyric, carbonic, formic, lactic, oxalic, succinic, and valerianic acids. Some of these products, however, only occur in the secretions in cases of disease.

SECRETIONS, VEGETABLE. In the vegetable kingdom, the term *secretion* has a wider application than in the animal kingdom, and all substances which have been formed by the action of cells upon the compounds taken up as food (such as carbonic acid, water, and ammonia)—whether these substances form a part of the tissue of the plant, or are thrown out upon its surface—are equally considered as secretions. All the important vegetable secretions are compounds of carbon, hydrogen, oxygen, and nitrogen; sulphur being also present in some cases; and according to their functions they may be classed in two great divisions—viz., (1.) nutritive or assimilable secretions, and (2.) non-assimilable or special secretions.

1. The *nutritive* secretions are those substances which, having been formed within the plant, are used in forming its structures and constructing its general mass. The chief substances in this class are cellulose, the varieties of starch, the varieties of

sugar, the oils, and the so-called protein or albuminous bodies. The composition of these substances is extremely varied; thus, many of the volatile oils or essences contain only carbon and hydrogen; the sugars, starches, and cellulose, contain carbon, hydrogen, and oxygen, and are named ternary compounds; while the protein bodies contain carbon, hydrogen, oxygen, and nitrogen, and, in some cases, sulphur.

2. The *non-assimilable* secretions are only found in certain parts of the plant, and they receive their name from their never being converted into the nutritive secretions. The principal members of this class are the colouring matter of plants (chlorophyle and its modifications); the substances which, when extracted from plants, are of service as dye-stuffs (the *chromogens* or colour-formers of recent chemists); the organic acids, which constitute a somewhat numerous group, and of which oxalic acid (occurring in rhubarb, sorrel, &c.), tartaric and racemic acids (in the grape), malic acid (in the apple and gooseberry), citric acid (in the orange, lemon, lime, and red currant), gallic acid (in the seeds of the mango), meconic acid (in the opium poppy), and tannic acid (in the bark of the oak, elm, &c.), may be taken as well-known examples; the vegetable alkalies or alkaloids, such as morphia, strychnia, quinia, &c.; the volatile oils; and the resins.



SECRET WRITING, or SYMPATHETIC INK. See INK.

SECRO'LE, a small town of Bengal, British India, three miles north-west of Benares, contains most of the civil establishments, the military cantonments, and the residences of most of the British population connected with Benares. The residences or bungalows are handsome and substantial, but are scattered about among the groves and gardens which surround the military cantonments. The latter, which are capable of containing three or four regiments, are traversed by a small stream, the Burnah Nuddee. Among the public buildings are a Christian church and chapel, a court of justice, the treasury, the jail, and a mint. S., which may be considered as the British quarter of Benares, was the headquarters of the Benares division of the Bengal army, and here, on the 4th June 1857, the 37th Bengal Native Infantry, the 13th Irregular Cavalry, and a portion of the Loodianah Sikhs, in all 2000 men, mutinied; but being charged by Colonel (afterwards Brigadier-general) Neill at the head of 240 men of the Madras and Queen's armies, and a few faithful Sikhs and Irregulars, they were compelled to take to flight with the loss of about 200 men, after killing two of their own British officers and two privates of Neill's force.

SECTION, in Architecture, the delineation of buildings on a vertical plane through any part of them—as a *plan* is the horizontal projection. Sections are of great use in practice in shewing the thickness of walls, the construction of floors, roofs, &c., and the forms and dimensions of every part of the interiors of buildings. Sections may also be used to shew the furniture, drapery, &c., of rooms. These are called furnished sections. All mouldings, cornices, &c., are drawn in section or profile, full size, for the guidance of the workmen.

SECTOR, in *Geometry*, is a portion of a circle included between two radii and the intercepted arc of the circumference. The area of a sector is equal to that of a triangle whose base is equal in length to the intercepted arc, and whose perpendicular height is equal to the length of the radius.

SECTOR, in *Practical Mechanics*, an instrument of considerable utility in rough mathematical drawing, consists of two strips of wood, ivory, or metal jointed together like a carpenter's foot-rule. It is absolutely necessary for the correctness of the instrument that the centre of the axle of the joint should be accurately at the inner corner of each slip (as shewn in the figure), so that it will always be the vertex of a triangle of which the inner edges (and consequently any of the corresponding pairs of lines drawn from the joint obliquely along the rule) form the two sides. These oblique lines, which are drawn on both sides of the instrument, and converge from the extremities of the two strips to the centre of the joint, are graduated in different ways, so as to give, on each limb, a line of equal parts, a scale of chords, scales of sines, tangents, and secants, a line of polygons, &c. (all of which are graduated from the centre of the hinge, which is their zero point), besides a number of common scales on the blank portions of the sector. The special use of this instrument is in the finding of a fourth proportional to three given quantities, and the operation is performed as follows: If the fourth proportional to 18, 16, and 81 is required, find the graduation indicating 18 on each limb; then obtain, by means of a pair of compasses, the length from 0 to 16, and open out the instrument till the two 18 points are as far apart as the distance given by the compasses; then, by measuring with the compasses the distance of the two graduations indicating 81, and applying the compasses to the scale, we obtain the fourth proportional required. It will be seen that this instrument merely supplies a mechanical mode of constructing two similar isosceles triangles, one of which has all its sides, and the other has only its equal sides given, the other side or base, which is formed by the sector, and read off by aid of the compasses and scale, being, from the very nature of similar triangles, the fourth proportion required. This instrument becomes more inaccurate as the angle formed by the limbs increases. The sector is said to have been invented by Guido Ubaldi about 1568, though Gaspar Mordente of Antwerp describes it in 1584, and attributes its invention to his brother Fabricius in 1554. It was described by several German and English writers in the same century, and again by Galileo, who claimed to have invented it in 1604.

Sector.

SE'CULAR CLERGY. See REGULAR CLERGY.

SE'CULARISM is the term applied to a system of ethical principles begun to be advocated about 1846 by G. J. Holyoake. As the system has a considerable number of adherents, and comes not seldom into public notice, a brief account of its leading doctrines is here given. As in similar cases, we allow a believer in the doctrines to speak for himself.

The Secular is defined as that which pertains to this life, and is treated as a thing apart; as independent of, rather than as necessarily opposed to, any other mode of thought and duty. Secularism, as regards opponents, claims that to ignore is not to deny. As the geometrician ignores chemistry or metaphysics, without a thought of denying them, so secularism, which concerns itself with this world, refuses to be held as conflicting with that 'other-worldliness,' which, if demonstrable, must be based on an experience to which secularism makes

no pretension, and towards which it considers itself to incur no responsibility. Secularism commences by laying down the proposition that intelligent sincerity is sinless. It does not maintain that even intelligent sincerity is errorless, but that it is without conscious guilt, even when it is, as it may be, dangerously mistaken. The conscience thus educated, Thought may be intrusted to inquire, and the search for Truth may be begun.

Secularism takes the term Free Thought as expressing the central idea which it inculcates. It defines Free Thought as the unrestricted application of the powers of the intellect to any subject—the absence of any threat or penalty, legal, spiritual, or social, for the exercise of thought. The Free Thought it inculcates is not lawless thought; it is guided by methods of logic, limited by evidence checked at every step by experience, which is omnipresent, and corrected by the results of science. Free Thought is not the rebellion, but the judicial action of the understanding. Reason—the faculty of following the pathway of facts—does not despise intuition, nor instinct, nor the voice of nature, nor authority; it uses, but revises them; it does not pretend to be infallible, but to be the best arbiter we have. To the conception of Free Thought is also necessary the Free Publication of Opinion; for no one could profit by the thought of other minds unless it was freely communicated. Hence the diffusion of thought becomes an obligation on each thinker, and silence or supineness a social crime. Again, Free Thought that would command respect must be submitted to Free Criticism. Thought is often foolish, often mischievous, and sometimes wicked, and he alone who submits it to free criticism gives guarantees to society that he means well, since by criticism comes the exposure of false or foolish opinions; and the right of criticism is the sole protection of the public from error. Free Thought must end in the Free Action of opinion, since he thinks to no purpose whose thought is inapplicable to conduct; and he withholds the sign of his own sincerity who does not unite his thought with action. Such is that education in Free Thought which secularism attempts.

It holds that Scepticism is the pathway to affirmative truth. So far from being a crime, scepticism is scrutiny. So far from being the end, it is the beginning of inquiry—the first condition for the recognition of unknown truth. He who would be master of his own mind, and know what is in it, and who would have no principles there but those which are pure, true, and reliable, must refuse to believe anything until he is compelled to believe it; it being no more safe to keep one's mind open to all notions, than to keep one's door open to all comers. It is clear that the use of Free Thought may be a nuisance, a terror, or an outrage, unless Courtesy takes care of it. Therefore secularism provides that advocacy shall be directed to the exposure of error and the elucidation of truth, without moral imputation upon those whose opinions are controverted; and contends that all advocacy, wanting in consideration towards others, shall be regarded as a crime against Free Thought. The quality of the thought, and not the motive of it, is the proper and sufficient subject of discussion.

Secularism further imposes upon the action of Free Thought the limit that every one shall concede to others the liberty he claims for himself, and shall permit to others, and shall recognise in each individual, 'liberty of action in all things by which others are neither injured nor damaged.' Secularism, regarding the one object of all Free Thought as the attainment of truth, finds in the study of nature its immediate sphere of exercise. Free Thought is prompted by a desire to fathom the knowable; and nature and human life are the immediate sources of truth and duty, which it most concerns man to master. Therefore respect for this life, respect for pure physical conditions, respect for the moral capacity of human nature, are conditions of secular belief. Secularism is not committed to denying that there is other good—it does not meddle with that question; it says whether there be other good or not, the good of the present life is good, and it is good to seek that good. It holds that the secular is sacred, and seeks 'to find that material condition in which it shall be impossible for man to be depraved or poor.' It does not say that all things are material, or that there are no spiritual agencies; it does not enter upon these propositions, but confines itself to shewing that there are material agencies in this life, whatever else there may be, and that these, as far as they can be discovered, are the calculable forces of the world, which cannot be neglected without folly or hurt, and that it is wisdom, mercy, and duty to attend to them. Without entering upon the question of the interference of Providence, secularism contends that Science is practically the providence of life: that conscience is higher than consequence; that deliverance from calamity is more merciful than any system of consolation which only acts when calamity has occurred; and that it is not the pursuit of happiness, but the performance of duty, which is the end of life. Secularism proceeds in the path of Positive Philosophy, not seeking for errors but for truth; not busying itself with negations, but with affirmations. In sacred writ it seeks for guiding truth and thought which commends itself to reason and experience, accepting the intrinsically true, without entering upon the vexed questions of inspiration or authenticity. Whatever principles secularism inculcates, they are affirmative in their nature, relate to the welfare of humanity, and are determined by considerations purely human.

There is unquestionably a vast outlying class in every European country, and especially in British Hindustan, who are without the pale of Christianity. They reject it, they dislike it, or they do not understand it. Secularism is intended for these, and for all who find theology indefinite, or inadequate, or deem it unreliable. The object of secularism is to afford these classes a knowledge of principles addressed to their common reason and intelligence, by an appeal to principles of a secular nature, common to humanity in every state and clime. It may be a misfortune that the principles of theism, or the acceptance of the Bible, cannot be rendered promptly acceptable to them. Since, however, this is not the case, it must be of advantage to interest them in rules calculated for the moral guidance of their conduct. Upon these Christianity may be, if shewn to be tenable, subsequently superinduced. The principles of secularism are intended to constitute an education of the working-classes, which begins with their reason, grows with their intelligence, and ends only with death.

Secularism is not an argument against Christianity, it is one independent of it. It does not question the pretensions of Christianity; it advances others. Secularism does not say there is no light or guidance elsewhere, but maintains that there is light and guidance in secular truth, whose conditions and sanctions exist independently, act independently, and act for ever. Secular knowledge is manifestly that kind of knowledge which is founded in this life, which relates to the conduct of this life, conduces to the welfare of this life, and is capable of being tested by the experience of this life. Geometry, Algebra, Botany, Chemistry, Navigation, Political Economy, Ethics, are secular subjects of

instruction (distinct albeit from secularism which includes the education of the conscience). They are founded in nature, they relate to the uses of this life, promote the enjoyment of this life, and can be tested by personal experience. That which is secular can be tested in time; that which is theological is only provable after death. If a sum in arithmetic is wrong, it can be proved by a new way of working it; if a medical recipe is wrong, the effect is discoverable on the health; if a political law is wrong, it is sooner or later apparent in the disaster it brings with it; if a theorem in navigation is erroneous, delay or shipwreck warns the mariner of the mistake; if an insane moralist teaches that adherence to the truth is wrong, men can try the effects of lying, when the disgrace and distrust which ensue soon convince them of the fallacy; but if a theological belief is wrong, we must die to find it out.

The standard of secularism is utilitarian. Utility is made the test of right, not the utility which is sensual and selfish, but that which takes into account the highest attributes and noblest aspirations of humanity (see UTILITARIANISM). It is not the agent's own happiness, but the happiness of others which the utilitarian is bound to promote. The adoption of this rule makes intelligence a necessity. Secularism is not sceptical. It seeks everywhere positive truth, and regards doubt as a difficulty and a danger. It is not infidel, for that is a state of mind treacherous to the truth, and truth is the first thing to which secularism teaches allegiance. It is not atheistic, atheism being alien to secularism, which concerns itself with the affirmative. Secularism might call itself religious, if it were allowable to use the term without including some distinctive theory of theism, which is equally excluded from the subject-matter of secularism, as not coming within the region of positive knowledge. Nothing in secular morals can be insisted upon with effect, save those statements which appeal to the common experience, and with which you can dare the judgment of mankind; but if that may be called religious, which appeals to demonstrative intelligence, which addresses itself to the conscience, which inculcates love, and truth, and justice; which claims service and endurance from all men; which places happiness in duty, and makes the service of humanity the one object of life, and the source of consolation in death, then secularism may be so defined, and in this sense it has been described in the following definitions:

Secularism is the religion of the present life: it teaches men to seek morality in nature, and happiness in duty; guiding the conduct and educating the conscience of those who do not know, or who, from conscientious conviction, stand apart from Christianity. Secularism teaches a man to acquit himself well in this world as the purest act of worship, to study the truth, to judge by reason, to regulate human interests by considerations purely human, and to act on that rule of utility which conduces to the greatest good of others; thus endeavouring to deserve another life by the unhasting, unresting pursuit of duty in this.

SECUNDERÁBA'D (more correctly Sikandarábád), a large town, and an important British military cantonment in the Nizam's Dominions, India, six miles north of Haidarábád. On the north-east are two singular granite hills, large, hemispherical in shape, completely isolated, and having on their summits the tombs of Fakirs, which are visited by a great number of pilgrims each year. The cantonment consists of a curved, irregular street, three miles in length, with the officers' houses ranged on either side. There are numerous barracks, and good hospital accommodation. There are numerous tanks in the vicinity, and the water is good. The mean annual temperature is 81° 30′, and the climate is unhealthy—though less so now than formerly—during the rainy season. Pop. of S., 40,000.

SECURITY, in Law, means some deed or instrument affecting real or personal estate, the object of which is to secure the payment of money or other primary debt or obligation. Such are Bonds (q. v.) and Mortgages (q. v.). See also HERITABLE SECURITIES.

SEDAN, an ancient, manufacturing town of France, in the dep. of Ardennes, and a frontier fortress of the third rank, on the right bank of the Meuse, 163 miles by railway north-east of Paris. The cloth manufacture employs a large portion of the population, which amounts to about 16,000. On September 1, 1870, the French army under MacMahon was here defeated with a loss of 30,000 prisoners, and on the 2d the Emperor Napoleon III. surrendered his person and 100,000 soldiers to the King of Prussia.

SEDA'N CHAIR, a portable covered vehicle for carrying a single person, borne on two poles by two men. The name is derived from the town of Sedan, in the north of France, where this species of conveyance is said to have been invented. It is said that the Duke of Buckingham was in the practice of using one in the reign of James I., a proceeding which gave general offence, it being made matter of public remark, that this royal favourite used his fellow-countrymen to do the work of beasts. The general introduction of sedan chairs into England dates from 1634, about the same period that hackney coaches came into use. Sedan chairs were largely used during the greater part of last century, being found very well adapted for transporting persons, in full dress, to public and private entertainments. Not only were there numerous public conveyances of this kind in London and all considerable towns, but the owner of every large mansion had his private sedan handsomely fitted up. In Edinburgh, a century ago, sedan chairs were far more numerous than hackney coaches, and were almost all in the hands of Highlanders. Sedans are now seldom seen except for the transport of the sick.

SE′DATIVES are medicines which exert a direct or primary depressing action upon the vital powers, without inducing any subsequent excitement. The diseases in which sedatives are employed are chiefly those of over excitement of the nervous and circulating systems; and as some of the members of this class (hemlock, for example) act directly on the nervous system, while others (foxglove, for example) more immediately act upon the heart, it is necessary to be able to determine the kind of sedative suitable for each individual case. Inflammatory fever presents all the conditions in which sedatives are likely to be of service. 'The excited heart, elevated temperature, hard and unyielding pulse, and the disordered state of the special nerves, call for the administration of remedies fitted to appease their excited energy, and the great improvement which, in such a case, follows the use of *blood-letting*, *tartar emetic*, and *digitalis*, bears evidence to the correctness of our practice.' (Ballard and Garrod's *Elements of Materia Medica*, p. 11.) The following are the most important members of this class: aconite, carbonic acid (applied locally in cases of irritable bladder or womb, or to painful ulcers), chloroform (especially when inhaled), conium, digitalis, hydrocyanic acid, and tobacco.

SEDGE. See CAREX.

SEDGWICK, an American family, distinguished in politics, law, and literature.—THEODORE S.,

statesman and jurist, was born at Hartford, Connecticut, May 1746. He was descended from Robert Sedgwick, a major-general of the army of Cromwell. Educated at Yale College, he adopted the profession of law, and removed to the western part of Massachusetts, where he was a member of the Colonial Assembly. Though a loyalist in feeling at the outbreak of the American revolution, he took the part of his country, and served as an aide-de-camp to General Thomas in the unfortunate expedition to Canada. In 1785, he settled at Stockbridge, Massachusetts, where his descendants now reside, became a member of the Continental Congress, and took an active part in suppressing Shays' rebellion. He remained in congress as representative or senator until 1799, and in 1802 was appointed judge of the Supreme Court of Massachusetts, and was a prominent member of the old Federalist party, and an early opponent of slavery. He died at Boston, January 24, 1813.—THEODORE S., American lawyer and writer, son of the preceding, was born at Sheffield, Massachusetts, December 1780. Like his father he was bred to the legal profession, and in 1801 settled at Albany, New York, where he remained in successful practice until 1821, when he retired to Stockbridge, advocating, as a popular speaker, the interests of a scientific agriculture, free trade, temperance, and anti-slavery, and wrote *Public and Private Economy, illustrated by observations made in Europe in* 1836—1837 (3 vols., 12mo, New York, 1838). He died of a stroke of paralysis, after making a public speech at Pittsfield, Massachusetts, November 7, 1839.—SUSAN RIDLEY S., wife of the preceding, descended from an old English Border family, and proud of her relationship to Bishop Ridley, was a daughter of William Livingston, governor of New Jersey. She is the author of *The Morals of Pleasure* (1829); *The Young Emigrants*, and *The Children's Week* (1830); *Allan Prescott*, a novel (1834); *Alida* (1844); and *Walter Thornley*, a novel written in 1859, when she was more than 70 years old. She resides on the family estate at Stockbridge.—CATHERINE MARIA S., American authoress, daughter of Judge Theodore Sedgwick, was born at Stockbridge, near the close of the 18th century. In 1822, she published *A New England Tale*, which was followed, in 1824, by *Redwood*, a novel so popular that it was reprinted in England, and translated into several of the continental languages. This was followed by *Hope Leslie, or Early Times in America* (1827); *Clarence, a Tale of our Own Times* (1830); *Le Bossu* and *The Linwoods* (1835); and these by a series of popular stories, illustrating morals and domestic economy, entitled *The Poor Rich Man and the Rich Poor Man*, *Live and Let Live*, *Means and Ends*, *Home*, &c. She also contributed a 'Life of Lucretia Maria Davidson,' to Sparks's *American Biographies*. In 1841, on her return from a tour in Europe, she published *Letters from Abroad to Kindred at Home;* in 1845, *Wilton Harvey and other Tales;* followed by *The Morals of Manners*, and *Married and Single*. She also edited, and was an active contributor to some of the leading American periodicals. She died in 1867.—THEODORE S., an American lawyer, son of the second Theodore S., was born at Albany, January 27, 1811, was educated at Columbia College, and admitted to the bar in 1833; and excepting three years spent at Paris, as secretary of the American legation, continued in successful legal practice until 1850, when he again visited and made an extensive tour in Europe. He steadily declined to engage in politics, and refused all offices tendered him, until, in 1858, he accepted that of United States attorney for the southern district of New York. Among his writings are, a standard *Treatise on the Measure of Damages;* a work on *The Interpretation and Application of Statutory and Constitutional Law;* the *Memoirs of William Livingston*, his grandfather; *The Life and Works of William Leggett*, and various occasional addresses. He died at Stockbridge, December 9, 1859.

SEDI'TION (Lat. *seditio*, from *se*, apart, and *ire*, to go), a general name given to such offences against the state as fall short of treason. In the law of England, it is not a strictly technical word. Writing, publishing, or uttering words tending to excite subjects to insurrection, though not urging them to rebellion or total subversion of the government, come under this denomination. There are various English statutes (as 39 Geo. III., c. 70; 57 Geo. III., c. 19; and 60 Geo. III. and 1 Geo. IV., c. 8) directed against particular acts of sedition, such as seditious libels, and seditious meetings or assemblies, which are punishable as misdemeanours. Act 36 Geo. III., directed against all seditious practices and attempts tending to high treason, is extended to Ireland by 11 Vict., and additional provisions are added to it. By this latter act, the compassing or devising, either to depose the Queen; to levy war against the Queen, for the purpose of changing her Majesty's measures, or constraining or overawing parliament; or to move any foreigner to invade the Queen's dominions, is made felony, punishable by transportation for life, or for a period not less than seven years, and that even though the facts should amount to treason.

In Scotland, sedition is distinguished from Leasing-making (q. v.), in so far as the object of the latter is to disparage the private character of the sovereign, while the former crime is directed against the order and tranquillity of the state. The punishment of sedition, formerly arbitrary, is now restricted to fine and imprisonment.

SEDU'CTION, in point of law, is the taking of an unmarried woman's chastity without marriage, and under circumstances of fraud. It is not a criminal offence unless violence is used, and resistance overcome, or the age of the female is under 21, in which cases the offence is Rape (q. v.) or Abduction (q. v.). In England, where no force has been used, no action at law can be maintained by the female seduced, however deceitfully the man may have acted. But if the female is a servant, either to her father or mother or a third party, then the master or mistress can sue the seducer, provided any loss of service has been caused by the seduction, such as her absence when lying-in of a child. Though, strictly speaking, the damages recovered by the master or mistress, in such a case, should be measured solely by the pecuniary value of the services lost, yet it is an inveterate practice for juries to give damages greatly beyond that amount, especially where the father or mother sues, and the conduct of the man has been base and heartless. In Scotland, the woman can sue in her own right for damages if deceit has been used, but the difficulty of establishing that the deceit was the sole cause of the injury, prevents such actions from being common. The remedy there more frequently resolves itself into an action for breach of promise of marriage, or for declarator of marriage, or for filiation and aliment.

SE'DUM, a genus of plants of the natural order *Crassulaceæ*, having the calyx in 4—8 (usually 5) deep segments, which often resemble the leaves, the same number of spreading petals, twice as many stamens, and 4—8 (usually 5) germens, each with a nectariferous scale at the base. The species are numerous, with succulent, often roundish, leaves; and pretty, star-like flowers. Many of them grow on rocks, whence the English name STONE-CROP. They are natives of the temperate and

cold parts of the northern hemisphere; some are British. They have no important uses; some are refrigerant, others are acrid. Among the British species is *S. Telephium*, popularly called ORPINE, sometimes used as a diuretic; and *S. acre*, the most common, whose brilliant yellow flowers adorn the tops of old walls, the débris around quarries, &c.

SEE (Lat. *sedes*, a seat), in ecclesiastical use, properly signifies the seat or chair (*cathedra*), sometimes also called 'throne,' of a bishop. Popularly, however, and indeed by universal usage, it is employed to designate the city, and thence, at least in popular language, the entire diocese, in which the seat of the bishop is placed, and over which, consequently, his episcopal jurisdiction extends. Sees have always been fixed, at least in their primitive establishments, in some city or considerable town; and it is to be observed that the name of a see is always taken not from the district governed by the bishop, but from the city or town. Sees *In Partibus Infidelium* (q. v.) still retain their ancient names, although in very many cases not merely the cities themselves, but even all traces of the Christian religion, in the sites upon which they anciently stood, have disappeared. In the Roman Church, the pope alone establishes sees, and alters their distribution and their local limits and boundaries; but these changes are not made except in extreme cases (such as that of the French Revolution) without the consent of the actual bishop. In the Anglican Church, this is done by the authority of the legislature.

SEED, in Phanerogamous Plants, that part which may in some measure be regarded as corresponding to the perfectly developed impregnated *ovum* of animals, and which is the utmost effort made by the plant for the reproduction of its species. It is the perfectly developed Ovule (q. v.). Whilst one cell of the interior of the nucleus (see OVULE) greatly enlarges, the other cells are forced back; the interior of the nucleus thus becomes a cavity (the embryo sac), and Fecundation (q. v.) now taking place by means of the pollen, the primary cell is formed, which grows to form the *embryo*. As the fertilised ovule is developed into the ripe seed, the *foramen* (see OVULE) or *micropyle* closes completely; but its place is commonly marked in ripe seeds by a little cicatrix. In the ripe seed, the integuments of the ovule, more fully developed, form the covering (*spermoderm*); whilst the *nucleus* is either entirely converted into the Embryo (q. v.), or also into an unorganic cellular mass called the Albumen (q. v.), which is, in an economical point of view, the most important part of many seeds, as of those of the cereal grasses. The embryo, which with respect to the reproduction of the plant, is the most essential part of the seed, is developed to various degree in different plants—which is also the case in different animals, and even in those of the same class, as in mammalia; but in general, the *radicle* may be distinguished in it—the beginning of the root or descending axis of the new plant, and the *plumule* or *gemmule*—the beginning of the stem or ascending axis, as well as the *cotyledon* or cotyledons, provided for the nourishment of the new plant in its youngest stage. When the embryo is accompanied with albumen, it is sometimes completely enclosed in it; sometimes it lies at the side of the albumen; and sometimes it surrounds the albumen like a ring, or even completely. Sometimes, but rarely, the embryo is not well developed in ripe seeds, so that its parts cannot be distinguished, as in the *Orchideæ*, in which it appears as a roundish or oval, uniform, little cellular mass. In germination, the embryo breaks through the covering of the seed, and develops itself into the new plant.

Seeds are either *sessile* or *stalked*. The stalk is of various length, and is formed of the *funiculus* or *umbilical cord;* the place at the base of the seed, by which it is affixed to the inside of the fruit, of to the end of the *funiculus*, being called the *Umbilicus* or *Hilum*. When the seed is perfectly ripe, it has no further need of connection with the parent plant, and the *funiculus* dries up, leaving the *hilum* a mere scar.

Besides being enclosed in a capsule, or in a succulent fruit, &c., the most essential parts of the seed have coverings of their own, which are reckoned as belonging to the seed itself. Its general covering is called the *spermoderm* (Gr. *sperma*, seed, *derma*, covering), which consists of an external membrane, the *testa* (Gr. shell) or *episperm* (Gr. *epi*, upon) and an internal membrane, the *endopleura* (Gr. *endon*, within, *pleura*, side). Sometimes there is within the episperm a fleshy layer, called the *sarcosperm* (Gr. *sarx*, flesh). The Aril (q. v.) is a comparatively rare additional covering.

The seeds of phanerogamous plants afford characters which distinguish two great classes as *Monocotyledonous* and *Dicotyledonous* (see COTYLEDON). Very few plants have more than two cotyledons (seed-lobes). It is the case, however, with some of the *Coniferæ*. Cryptogamous plants are also designated *Acotyledonous*, as having no seed-lobes; and the name *Spore* (q. v.) is distinctively given to their seeds.

Seeds retain their vitality very long; but the time seems to be very various with the seeds of different plants, and in different circumstances. The grains, or seeds of cereal grasses, are probably excelled in this respect by none; grains of maize found in the tombs of the Incas have been made to vegetate; and also, it is said, grains of wheat taken from Egyptian mummies, although of this there is some doubt. After the great fire of London in 1666, plants not previously common sprang up abundantly on the waste ground; certain plants previously unknown there are sure to appear after a fire in the American forests; and instances are constantly occurring of a deep trenching of land or a turning up of soil by railway or other operations, producing a crop of some kind of plant previously unknown or rare in the locality. Thus the writer of this article has seen plants of the Milk Thistle appear on rubbish thrown out from the foundation of a house in Peeblesshire, where there was no other Milk Thistle in the neighbourhood. And in Paisley Moss, in Renfrewshire, willows spring up in the ditches which are cut for drainage, from the surface of the soil which underlies the moss or peat. It is difficult to conjecture how long the seeds, in such cases, may have retained their vitality.

Exposed to the air, however, seeds generally lose their vitality in a few years. Some kinds retain it much longer than others. Seeds which abound in fixed oil seem to lose it more quickly than others.

In conveying seeds from one part of the world to another, and through great diversities of climate, it is desirable to have them as closely secured from the air as possible. But it has been found that of seeds brought from the Botanic Garden at Calcutta to Scotland, round the Cape of Good Hope, with no other care than would be used in sending a parcel from a seed-shop to a neighbouring garden, the greater part readily vegetated.

SEE'LAND (Dan. *Själland*), the largest and most important island of Denmark, lies between the Cattegat and the Baltic, and is separated by the Sound from Sweden, and by the Great Belt from Fünen. Length, 78 miles; extreme breadth, 70 miles.

area, 2672 sq. m.; pop. in 1868 (including the pop. of Möen, with 15,000 inhabitants), 619,198. The surface is almost flat; the coasts, which are rock-bound on the south-east, are indented by bays and fiords, the chief of which is the Roeskilde-Isefiord in the north. The rivers are small, the largest being only 50 miles long; there are several lakes, and all the waters abound in fish. The island contains several beech-forests, is exceedingly fruitful in corn, and breeds excellent horses and cattle. Agriculture and cattle-breeding are the principal employments of the inhabitants. The chief place is Copenhagen (q. v.), the capital of the country, on the east coast, and from this city, lines of railway traverse the island to Elsinore in the north, and to Korsör in the south-west, on the coast.

SEER. See PROPHET.

SE'GGAR, a vessel used by potters to protect delicate articles from the too fierce action of the fire in the kiln. See POTTERY.

SE'GMENT (Lat. *segmentum*, a part cut off) is, in Geometry, a portion cut off from a circle by a line, or from a sphere by a plane. When the angle subtended at the centre of a circle by the segment, and the radius, or when the chord of the segment and its height, are known, the length of the arc of the segment and its area can be determined with as much accuracy as the circumference and area of the whole circle. See SPHERE.

SE'GNO (Ital. sign), a word used in musical notation in connection with marks of repetition. When a part is to be repeated, not from the beginning, but from some other point, the mark 𝄋 is placed over the point where the repetition is to commence, and the words *Dal Segno* (or *d. s.*) are written at the close of the part to be repeated.

SE'GO, an important town of Western Africa, capital of the state of Bambarra, stands on the Niger, here called the Joliba, in lat. 13° 5′ N., long. 7° W. Its streets, which are winding, have a breadth of from 24 to 26 feet, and are extremely clean. The palace of the king is large enough to accommodate 2000 men and 500 horses. The houses are built of clay, and are flat-roofed, and the royal residence differs from the other dwellings only in size. The country in the vicinity is well cultivated, and the town is the seat of considerable traffic. Mungo Park, from whom we derive almost all the knowledge we possess of S., here first beheld the Joliba. Pop. estimated at 30,000.

SEGO'RBÉ, a small town of Spain, in the modern province of Castellon, on the right bank of the Palancia, in a valley renowned for the beauty of its scenery and for its amazing fertility, 20 miles north-west of Murviedro. It stands on a hill between two castles, and contains stately houses, numerous churches, and a cathedral. Brandy-distilling is carried on to a great extent, and there are flour and paper mills. Pop. 6200.

SEGO'VIA, an interesting city of Spain, capital of the modern province of the same name (see CASTILE), stands on the Eresma, by which it is nearly encircled, 47 miles north-north-west of Madrid. It occupies the top of a rocky knoll, 3300 feet above sea-level, is surrounded by picturesque walls with round towers, and consists of narrow uneven streets, with old, quaint, and stately houses, 24 parish churches, and 21 convents. The Alcazar, or castle, is perched on the west extremity of the rocky height, and was originally Moorish, but repaired magnificently in 1452—1458. The cathedral of S., a noble specimen of florid Gothic, is one of the finest in Spain. The present building was begun in 1525. The square cupola-crowned tower is 330 feet high, and the prospect from this elevation is superb. The grand aqueduct of S., supposed to have been built in the time of Trajan, is believed to be the most important Roman structure in Spain. It consists of two rows of arches, the one resting upon the other, from 2500 to 3000 feet in length, and 102 feet high. There is a mint here for coining copper money. Wool-scouring and the manufacture of woollen fabrics are languidly carried on. Pop. 10,339.

S. was a place of importance during the time of the Romans; was the seat of immense cloth-manufactures in the time of the Moors, and was frequently the residence of the kings of Castile and Leon. Charles I. of England lodged at the Alcazar, September 13, 1623, and supped on 'certaine trouts of extraordinary greatnesse.' The unresisting town was entered in 1808 by the French, under Frere, and completely sacked.

SEGUR, the name of a French family, distinguished both in arms and letters. It is of Limousin origin, and was known there, it is said, as far back as the 9th century. The first, however, that specially merits notice was HENRI FRANÇOIS, Comte de S. (born 1689, died 1751), an able French general in the war of the Austrian Succession. His son, PHILIPPE HENRI, Marquis de S. (born 1724, died 1801), fought in the Seven Years' War, obtained the dignity of *Maréchal de France* in 1783, and outlived in his retirement the stormy scenes of the Revolution. The eldest son of this Philippe Henri was LOUIS PHILIPPE, Comte de S. (born 1753, died 1830), a vivid dashing sort of man, for some years ambassador at the court of St Petersburg, and a great favourite with Catharine II. Of impressionable fancy, full of enthusiasm for the 'philosophers,' the 'reign of reason,' and the 'new ideas' generally, he hailed the great Revolution with delight, but took no prominent part in it. His public career during the Empire was respectable, but not brilliant; but one notices with satisfaction that he retained in extreme old age that love of liberty that marked his early years; the last act of his life being an eulogium on the revolution of July. As a writer, S. has in wonderful perfection the national graces of style and spirit. Among his numerous writings are: *Pensées Politiques* (Par. 1795), *Histoire de Frédéric Guillaume II.* (Par. 1800), *Contes, Fables, Chansons et Vers* (Par. 1801), and *Mémoires ou Souvenirs et Anecdotes* (Par. 1824). He left two sons, OCTAVE and PAUL PHILIPPE, the latter of whom (born in 1780) was a general of the First Empire, took part in the fatal expedition to Russia in 1812, and wrote the story of the campaign, *Histoire de Napoléon et de la Grande Armée pendant l'année* 1812 (Par. 2 vols., 1824). The work has had an immense success, and has been translated into almost all the languages of Europe. Other works of the Comte Paul Philippe de S. are: *Lettre sur la Campagne du Général Macdonald dans les Grisons* (Par. 1802), *Histoire de Russie et de Pierre le Grand* (Par. 1829) *Histoire de Charles VIII., Roi de France* (Par. 1834); &c.

SEGU'RA, a river in the south-east of Spain, rises in the Sierra Seca, and after an east-south-east course of about 180 miles, enters the Mediterranean 27 miles below Orihuela. Ships unload at its mouth.

SEI'DLITZ POWDERS are composed of 120 grains of tartrate of soda and potash, and 40 grains of bicarbonate of soda reduced to powder, mixed and enclosed in a blue paper, and 35 grains of powdered tartaric acid in a white paper. The contents of the blue paper are dissolved in from half a tumbler to a

tumbler of water, and those of the white paper are then stirred in. The mixture should be taken while the effervescence from the liberation of the carbonic acid is still going on. These powders act as an agreeable and mild cooling aperient. If a stronger dose is required, either an increased quantity of the powder may be used, or a little sulphate of magnesia (about a drachm) may be added.

SEI'GNIOR, GRAND, a name sometimes given to the Sultan (q. v.) of Turkey.

SEINE, the metropolitan dep. of France, completely enclosed by the dep. of Seine-et-Oise, is a portion of the former province of L'Ile-de-France, and derives its name from that of its principal river (see SEINE, river). It is at once the smallest and the most populous dep. in France; its area is 183 sq. m.; its pop. (1866) 2,150,916, or 11,751 to the sq. mile. From south-east to north-west, the dep. is traversed a distance of 37 miles by the winding Seine, which receives the navigable Marne at Charenton, and the Bièvre at Paris. The surface is marked by undulations and low hills, the highest of which, Mont-Valérien, is only 446 feet above sea-level. The climate is pleasant and healthy. The scenery—of which the woods of Verrières, Meudon, and Saint-Cloud, together with those of Vincennes and Boulogne, transformed into parks, and watered by artificial rivers and lakes, are perhaps the most striking features—is remarkably pleasing. A network of canals and railways, the latter converging in the capital, afford easy means of transit in any direction. The soil is calcareous, and in the greater part, naturally infertile, but, owing to the skill of the farmers and gardeners, who obtain abundant supplies of manure from the metropolis, the country around Paris (q. v.) and its suburbs has been rendered remarkably productive. The culture of vegetables and fruits for the markets of Paris is one of the most important branches of husbandry. Enormous quantities of mushrooms are cultivated in the ancient quarries of Paris near Montrouge. Quarries abound, and are productive.

SEINE (anc. *Sequana*), one of the most important rivers of France, rises near Mont Tasselot, in the middle of the dep. of Côte-d'Or, and after leaving the northern boundary of that dep., flows west-north-west through the deps. of Aube, Seine-et-Marne, Seine, Seine-et-Oise, Eure, and Seine-Inférieure, to the English Channel, which it reaches at Havre, after a course of 470 miles. It passes the towns of Troyes, Méry—where, 350 miles from its mouth, it becomes navigable—Corbeil, Paris, Elbeuf, Rouen, and Havre. The source of the river is about 1420 feet above the level of the sea; but below Paris its current is slow, and its course to Rouen is marked by numerous windings. Its lower course also is banked by steep hills, which, while they are picturesque, are everywhere cultivated. The principal affluents are, from the right, the Aube, Marne, and Oise; from the left, the Yonne, Loing, Essonne, and Eure.

SEINE-ET-MARNE, an inland dep. in the north of France, is bounded on the E. by the dep. of Seine-et-Oise, and form a portion of that wide basin in the middle of which stands Paris. Area, 2214 sq. m.; pop. (1866) 354,400. The dep. owes its name to the two chief streams that water it, and of which the Seine flows through the southern, and the Marne through the northern part. There are no mountains, but ridges of low hills separate the fertile and extensive though not deep valleys. Timber is grown in every part; and among the forests is that of Fontainebleau. The soil is generally fertile. Of cereals, wheat is the principal crop. Vegetables and fruits are also largely grown, and the meadows and pastures, natural and artificial, are extensive and productive. The wines are mediocre in quality, but the grapes for the table, called the *Chasselas de Fontainebleau*, have a European reputation. The capital is Melun, and the arrondissements are Melun, Coulommiers, Fontainebleau, Meaux, and Provins.

SEINE-ET-OISE, a dep. in the north of France, encloses the metropolitan dep. of Seine (q. v.). Area, 2163 sq. m.; pop. (1866) 533,727. The great rivers are the Seine and Oise, which have numerous affluents. Extensive plains occupy the southern districts; but in the north, the country is much broken, and picturesque valleys and great forests occur. The soil is not in general very fertile; but owing to the vicinity of the capital the amount of produce is great. Among the minerals are several fine varieties of stone and fine clays. In addition to the usual branches of manufacture, porcelain is largely made at the famous Sèvres (q. v.) factories. The dep. is divided into the arrondissements of Versailles, Corbeil, Etampes, Mantes, Pontoise, and Rambouillet, and the cap. is Versailles.

SEINE-INFERIEURE, a maritime dep. of France, bounded on the north-west by the English Channel, and on the south by the dep. of Eure. Area, 2328 sq. m.; pop. (1866) 792,768. The Seine flows through the southern districts; but a number of important though small streams flow north-west across the dep. and fall into the Channel. The range of the hills of Caux extends from east to west, and to the south of it are rich pasture-lands, watered by the Seine and its affluents. Husbandry flourishes chiefly in the middle and in the east districts. The coasts are formed of chalk-cliffs, varying in height from 200 to 650 feet. The arrondissements are Rouen, Neufchâtel and Yvetot. The capital is Rouen, which communicates with Dieppe by a direct line of railway.

SEIR-FISH (*Cybium guttatum*), a fish of the family *Scomberidæ*, having finlets and the sides of the tail keeled, the teeth compressed and sharp. It inhabits the seas of the East Indies, and is one of their most valuable fishes. In size and form, it is very similar to the salmon, which its flesh resembles also in firmness and flavour, although of a white colour.

SEI'SIN. See SASINE.

SEISTA'N or HAMOON LAKE (anc. *Aria Palus*), a large, irregularly-shaped, shallow lake of Afghanistan, bordered with plantations of tamarisk and other trees, and enclosed by the province of Seistan. It is 25 parasangs (a parasang = 3·45 English miles) in length, and it varies from 6 to 12 parasangs in breadth. In most written accounts and maps, the form and position of the lake are inaccurately given. General Ferrier, perhaps the most recent explorer in this region, says that the lake is in lat. about 31°—32° N., and that it follows an oblique line, starting in the north at long. 60°, and terminating in the south in long. 59° E. Of the rivers which feed the lake, none, except the Helmund, contribute any waters during the summer, as in that season they are diverted and employed in the irrigation of the land. The lake, which has no outlet, overflows its boundaries, like the rivers which feed it, and irrigates and fertilises large tracts of country. It is only from four to five feet deep, and is gradually becoming shallower. Its waters, though not salt, are black, and disagreeable to the taste. The name Seistan is a corruption of Saghistan—i. e., the country of the saghis, a kind of wood which grows here in abundance, and

is largely used as fuel.—See Ferrier's *Caravan Travels* (Lond. Murray, 1856).

SE'JANT, or ASSIS (Fr.), in Heraldry, is the term of blazon applied to a beast in his usual sitting posture. A lion borne in full face, with his fore-paws extended sideways, is blazoned sejant affronté, as in the crest of Scotland.

Sejant affronté.

SEJA'NUS. See TIBERIUS.

SE'LBY, a market-town and river-port in the West Riding of Yorkshire, on the right bank of the Ouse, 12 miles south of York by railway. The ancient Gothic cross which adorns the market-place, and the character of the architecture of the houses, attest the age of the town. The magnificent parish church, 300 feet long by 60 feet wide, is part of an abbey founded by the Conqueror in 1068. The movable bridge across the river offers a passage to shipping, and the river is navigable to S. for vessels of 200 tons. Means of communication by railway and canal are abundant. There are iron and brass foundries, and slips for building river-craft; and the manufactures include sail-cloth, ropes, &c. Pop. (1861) 5271.

SELDEN, JOHN, an illustrious English scholar and lawyer, was born December 16, 1584, near Worthing, in Sussex, studied at Hart Hall, Oxford, for three years, and then removed, first to Clifford's Inn, London, and afterwards to the Inner Temple, for the pursuit of law. It was here that his great learning began to attract attention, and won for him the friendship of Camden, Usher, Sir Robert Cotton, and Sir Henry Spelman. S. wrote his first treatise, which related to the civil government of Britain previous to the Norman Conquest, and was entitled *Analecton Anglo-Britannicon*, in 1606, when only twenty-two years of age, though it was not published till nine years later. In 1610, appeared his *Jani Anglorum Facies Altera* (English translation 1683), giving an account of the common and statute law of English Brittany to the death of Henry II.; and in 1614 was published his *Titles of Honour*, a work still regarded as of high authority on the subject of which it treats. Three years later, appeared an erudite, but, judging from what Le Clerc says, not a very critical or well-digested, work on the Syrian gods, especially in their connection with the Old Testament, entitled *De Diis Syriis, Syntagmata Duo.* Next year, however, he excited great indignation among the clergy by his *Treatise of Tythes*, in which he endeavoured to prove that tithes are not due by divine right under Christianity, but solely because the law has imposed them. S. was assailed with diatribes, animadversions, additional animadversions, historical vindications of the *jus divinum* of tithes, &c.; but it does not appear that the arguments were very convincing to Selden. In 1621, he suffered a brief imprisonment for advising the parliament to repudiate King James's doctrine that their privileges were originally royal grants; in 1623, he was elected member for Lancaster, and from this period till his death, he took a considerable part in public affairs, yet not such as to materially interfere with the continuance of scholarly pursuits. S.'s political position is somewhat difficult to define. There is no doubt that he was sincerely attached to the cause of the parliament, and as sincerely opposed to the views of the court-party and the king. But he was above all things a constitutional lawyer, and derived his ideas of the rights of the subject from the history of the nation, and not from religious fanaticism or metaphysical considerations. Still, he 'loved his ease,' according to Clarendon (who has painted S.'s portrait in his usual fine style), and so let things be done without protest, of which he did not approve. Personally, he was rather a favourite with King Charles, on account of his learning and moderation. In 1630, he was committed to the Tower, for his activity in opposing the policy of the court, and remained a prisoner for four years, when he was released through the favour of Archbishop Laud and the Lord Treasurer; in 1640, he was chosen member for the university of Oxford; and now, when the struggle between the king and the nation began to grow dead-earnest, he was occasionally suspected of not being zealous enough by such as were themselves perhaps over-zealous. He threw the weight of his learning and argument into the scale against the bishops (towards whom, like Milton and other lay-champions of freedom, he felt a peculiarly strong antipathy), when the question came up as to their tenure of seats in parliament; he was one of those who drew up the articles of impeachment against Laud; he sat as a lay-member in the Assembly of Divines at Westminster, 1643, and perplexed his clerical colleagues sadly. In 1644, he was elected one of the twelve commissioners of the Admiralty; in 1646, the sum of £5000 was voted to him by parliament, in consideration of his services and sufferings; in 1647, he was appointed one of the university 'visitors,' and always used his influence to moderate the tyranny of his fanatical colleagues. After the execution of Charles (of which it is certain he strongly disapproved, as both unlawful and inexpedient), he took little share in public matters; and when requested by Cromwell to answer the *Eikon Basilike*, he refused. His death occurred November 30, 1654, in the house of Elizabeth, dowager-countess of Kent, with whom he had long lived in such intimacy that people said they were married. The principal writings of S., besides those already mentioned, are: *Marmora Arundelliana* (1629); *De Successionibus in Bona Defuncti secundum Leges Hebræorum* (1634); *De Successione in Pontificatum Hebræorum, Libri Duo* (Leyd. 1638); *De Jure Naturali et Gentium, juxta Disciplinam Hebræorum* (1640), a work more learned than critical (like most of S.'s biblical productions, who thought far too much of the opinions of the Rabbins); and *Uxor Hebraica*, *Mare Clausum* (1635), a reply to Grotius's *Mare Liberum* (treatises which originated in a dispute between the English and Dutch concerning the herring-fishery upon the British coast, to which the Dutch laid claim); *De Anno Civili et Calendario Judaico* (1646); *De Synedriis et Præfecturis Hebræorum* (1650 *et seq.*); besides a great variety of posthumous works, of which the most famous, and also the most valuable, is his *Table-talk* (recorded and published by his amanuensis, Richard Milward, in 1689), of which Coleridge says (with considerable exaggeration, however): 'There is more weighty bullion sense in this book than I can find in the same number of pages of any uninspired writer.' S. was highly esteemed by all his great contemporaries, both royalist and parliamentarian, on account of his integrity, candour, and vast erudition; but his moral courage or enthusiasm was not remarkable (except when tilting at the bishops—*then*, like Erasmus on the monks, he was quite heroic); and, on the whole, as compared with Milton, he occupies the level which Erasmus did

in relation to Luther. S.'s works were collected and published at London in three folio volumes, 1726.

SEL D'OR, a salt employed in Photography, originally to aid in fixing and improving the image on a Daguerreotype-plate, and more recently for toning positive paper-proofs. It is a double hyposulphite of gold and sodium, the constitution of which is expressed by the formula $Au_2S_2O_3.3Na_2S_2O_3.4H_2O$. It is formed when 1 part of chloride of gold in solution is added to 3 parts of hyposulphite of soda, also in solution. The hyposulphite of soda should be always in excess during the mixture, a condition which is secured by adding the chloride of gold to the hyposulphite of soda, and not *vice versâ*. The salt so formed is precipitated in fine, white, crystalline needles on the addition of alcohol to the above mixed solutions; these are collected on bibulous paper, and gently dried for use. Adulterations in the commercial article, which are unfortunately only too common, may be ascertained by precipitating, igniting, and weighing the gold contained in the sample it is desired to test. Nitric acid free from chlorine will decompose this salt, and precipitate its contained gold in the metallic form.

SELE'NÉ, the Greek name of the goddess of the moon; called also *Mene*, and in Latin, *Luna*. Her myth is differently told, but the most common account makes her a daughter of Hyperion and Theia, and sister of Helios (the Sun) and Eos (the Dawn); as sister of Helios, also called *Phoibos* (the Shining One), she had the name of *Phœbe*, and latterly was identified with Artemis (see DIANA), though the identification was never quite exact, as Artemis always retained her reputation for chastity, while S. had 50 daughters by her lover Endymion, and several by Zeus; one of whom was called *Erse* ('the Dew'), indicating the original physical character of the myth. In Art, the two are always distinct. S. is represented by the poets with long wings and a golden diadem, riding across the heavens in a chariot drawn by two white horses, cows, or mules.

SE'LENITE (Gr. *Selēnē*, the moon), a transparent and beautiful variety of Gypsum (q. v.), white, or tinged with green, gray, or yellow. It receives its name from its peculiar moon-like lustre. It is often crystallised in six-sided prisms, sometimes in lenses, and twin crystals and quadruple crystals occur. It is found in common gypsum, in rock-salt, in the Blue Clay of the south of England, &c. There is in the British Museum a splendid group of crystals of S., presented by Prince Albert. S. is easily cut, and is susceptible of being split into extremely thin plates, which are flexible, although not elastic. It was used by the ancients for some of the purposes for which we use glass. The Romans imported it from Spain, Cyprus, Cappadocia, and Africa. The hothouses of Tiberius were covered with it, and Pliny mentions that it was used in the construction of beehives by those who wished to watch the operations of the bees. It is used for making the finest kind of stucco, and the most delicate pastil colours. When burned, and perfectly dry, its powder is used for cleansing and polishing articles of gold and silver, precious stones, and pearls.

SELE'NIUM (symb. Se, equiv. 79.5, and sp. gr. 4·28) is one of the metalloid or non-metallic elements. At ordinary temperatures, it occurs as a solid of a dark-brown colour, and when broken, presents a conchoidal vitreous fracture; thin splinters of it are, however, of a dark-red tint when seen by transmitted light. It is tasteless and inodorous, a non-conductor of electricity; and like sulphur, to which it presents a remarkable analogy, it may be obtained in all three forms of atomic aggregation, being solid up to 392°, when it fuses into a fluid, which boils at 650°, emitting an inodorous vapour of a deep yellow tint. When heated in the air, S. does not very readily take fire, but it is combustible, and burns with a blue flame, while a portion of it is volatilised in red fumes, which emit an odour resembling that of bisulphide of carbon or garlic. The products of combustion are oxide of S. and selenious acid, the peculiar odour being probably due to the former.

S. is of rare occurrence in nature; it is chiefly found as a selenide in combination with lead, silver, copper, or iron; but it has also been discovered in the sulphur from the Lipari Isles, and in certain sulphides of iron, which accounts for its detection in sulphuric acid. It is unnecessary to enter into any description of the mode of isolating it; nor need we do more than simply mention that it forms three compounds with oxygen —SeO_2, oxide of S.; H_2SeO_3, selenious acid; and SeO_3, selenic acid; while with hydrogen it forms HSe, seleniuretted hydrogen, or hydroselenic acid, a colourless gas, which resembles, but is more offensive than sulphuretted hydrogen. Berzelius found that by the application of the nose to a bubble of it not larger than a pea, he was deprived of the sense of smell for several hours. It is prepared in the same way as the corresponding sulphur gas. As it is soluble in water, it should be collected over mercury.

S. was discovered in 1817 by Berzelius, who named it from *Selēnē*, the Gr. for 'the moon,' because it was associated with tellurium, which is named from *Tellus*, the Lat. for 'the earth.'

SELEU'CIA, the name of seven ancient cities of Asia, situated in Syria, Pisidia, Pamphylia, Cilicia, Caria, and Mesopotamia, and founded during the earlier existence of the dynasty of the *Seleucidæ* (q. v.). The most distinguished of these were: 1. SELEUCIA PIERIA, founded by Seleucus Nicator, on the sea-shore, about 4 miles north of the mouth of the Orontes, and strongly fortified. It was the seaport of Antioch, and became of great importance during the wars between the Seleucidæ and the Ptolemies for the possession of Syria. It rapidly declined under the Roman dominion. The ruins have been fully explored and described in modern times by Pococke (*Observations on Syria*) and Chesney (*Royal Geographical Society's Journal*, vol. viii.). Its once magnificent port is in such an extremely good state of preservation as to require few repairs to render it serviceable; and the remarkable tunnel of 1088 yards in length, which was excavated out of the solid rock, and formed the only communication between the city and the sea; and the remains of its triple line of walls, of its citadel, temples, amphitheatre, necropolis, &c., all attest the former importance and splendour of the city.—2. SELEUCIA ON THE TIGRIS, was also built by Seleucus Nicator, on the west bank of the Tigris, 40 miles (according to Strabo 33) north-east of Babylon, which was despoiled to supply materials for the construction of the new city. Situated in a district of great fertility, commanding the great trading routes of Assyria, Babylonia, and Western Persia, it rapidly rose to great wealth and splendour, supplanted Babylon as the capital of the eastern portion of the Seleucide monarchy, and when in the acme of its greatness, contained a population of more than 600,000. Even in Strabo's time, it was larger than Antioch in Syria, the greatest commercial emporium of Asia; and down to the period of its final destruction, the number of its inhabitants is said to have never fallen below half a million. During the decline of the Seleucide monarchy, it became independent, and formed, from its wealth and splendour, an irresistible bait to the robber tribes

of Southern Armenia and Media, who partially plundered it on more than one occasion. But its position on the confines of Persia, which gave it its greatness, was also the cause of its destruction; for when the Seleucide monarchy was swallowed up by the Romans, and the long and desolating struggle between the latter and Persia had commenced, S., placed between two fires, was speedily brought to ruin. It was burned by Trajan (116 A.D.), and a few years afterwards, by Lucius Verus; and when visited by Septimius Severus was as desolate as the mighty city it had supplanted. The Emperor Julian, on his expedition to the East, found the whole country round it converted into a vast marsh, the haunt of innumerable beasts of chase and wild-fowl, and the city itself completely deserted.

SELEU'CIDÆ, the dynasty of kings to whom fell that portion of Alexander the Great's immense and ill-compacted monarchy which included Syria, a large portion of Asia Minor, and the whole of the eastern provinces.

SELEUCUS I., surnamed NICATOR, the first of this line, was the son of Antiochus, a distinguished officer in the service of Philip of Macedon, and was born about 358 B.C. He was one of the conspirators against Perdiccas, and in the second partition of the provinces of Alexander the Great's kingdom, obtained Babylonia, to which, with the aid of Antigonus, he subsequently added Susiana; but a misunderstanding with that powerful chief having arisen, Seleucus took refuge in Egypt (316 B.C.). The victory gained by Ptolemy over Antigonus's son, Demetrius, at Gaza having laid open the route to the East, Seleucus returned to his satrapy, amidst the joyous congratulations of his subjects (312 B.C.). From October 1 of this year (the date of Seleucus's return to Babylon), commences the *era of the Seleucidæ*. Having next recovered Susiana, he conquered Media, and extended his power to the Oxus and Indus. Of his campaign against Sandrocottus (q. v.), there are few details extant. In 306 B.C., he assumed the regal title; and four years afterwards, joined the confederacy of Ptolemy, Lysimachus, and Cassander, against the now formidable Antigonus, deciding the battle of Ipsus (301 B.C.) chiefly by his cavalry and elephants. Being now, after Antigonus's death, the most powerful of Alexander's successors, he obtained the largest share in the conquered kingdom, a great part of Asia Minor and the whole of Syria falling to him. Towards the close of his reign, war broke out with Demetrius (now his father-in-law), and afterwards with Lysimachus, king of Thrace and the other part of Asia Minor, both contests terminating in the defeat and death of his opponents, and being followed by the acquisition of the rest of Asia Minor. He was assassinated (280 B.C.) by Ptolemy Ceraunus. Of Seleucus's personal character, little can be gathered from the fragments of his history which remain to us; according to Pausanias, he was the most upright of Alexander's successors, unstained by those crimes which have foully blotted the characters of the others; but of his consummate generalship and great political talents, we have sufficient proof. He pursued with great zeal the plan of 'Hellenizing' the East, by founding numerous Greek and Macedonian colonies in various parts of his dominions; he also built numerous cities, several of which —as Antioch in Syria, and Seleucia on the Tigris— rose to be among the most populous and wealthy in the world.—After the reigns of ANTIOCHUS I. (q. v.) and ANTIOCHUS II. (q. v.), SELEUCUS II. (246—226), surnamed CALLINICUS, obtained the throne; but having, at the instigation of his mother Laodice, murdered his stepmother Berenice, an Egyptian princess, he was driven from his kingdom by Ptolemy Euergetes (q. v.). However, he recovered his throne on Ptolemy's withdrawal; and though defeated in a great battle with the Egyptians, he succeeded in maintaining his hold of Syria and most of Asia Minor against both the Egyptians and his younger brother Antiochus, who exercised independent authority over part of Asia Minor. Antiochus was at a later period wholly defeated in Mesopotamia, and soon after murdered by robbers. Seleucus undertook a great expedition against the revolted provinces of Parthia and Bactria, but was totally routed by Arsaces I., king of Parthia; while, on the north-west, several provinces were wrested from him by Attalus, the king of Pergamus.—His sons, SELEUCUS III. (226—223), surnamed CERAUNUS, and ANTIOCHUS III. (q. v.), 'the Great,' were his successors, the latter being the first of the dynasty who came into collision with the Romans.—SELEUCUS IV. (187—175), surnamed PHILOPATOR, was eager to dispossess the king of Pergamus of the provinces which he had taken from the Syrian monarchy, but fear of the Romans prevented him from carrying out his design.—ANTIOCHUS IV. (q. v.), EPIPHANES (I.) ('the Illustrious'), conquered Cœle-Syria and Palestine from the Egyptians, to whom they had been given by his father; but retired from Egypt at the bidding of the Romans. He practised the most atrocious cruelties on the Jews, whose religion he endeavoured to root out, and introduce the Greek religion; but the heroic resistance of the Maccabees (q. v.) completely foiled his project. He died in a state of raving madness, which was attributed to his sacrilegious crimes by his subjects, who, in derision, converted his surname into EPIMANES ('the Madman').—The succeeding names of the dynasty were: ANTIOCHUS V., EUPATOR (164—162); DEMETRIUS I., SOTER (162—150), who regained Babylon, lost Judea, and was defeated and slain by the impostor Alexander Balas (150—146); DEMETRIUS II., NICATOR (146—138, 128—125), who overthrew the impostor, and was himself taken prisoner by the Parthians, Syria having been already seized by DIODOTUS, surnamed TRYPHON, who set up the puppet ANTIOCHUS VI., THEOS (144—142), and afterwards ascended the throne himself (142—137); ANTIOCHUS VII., SIDETES (137—128), who restored the royal line of the Seleucidæ; ANTIOCHUS VIII., GRYPUS (125—96), who was compelled to share his dominions with his half-brother ANTIOCHUS IX., CYZICENUS (111—95); SELEUCUS V. or VI., EPIPHANES (96—94), and ANTIOCHUS X., EUSEBES (95—83), who continued the division till 94 B.C., when the latter was victorious in a pitched battle, and seized the whole kingdom; for which, however, he was forced to fight with Philip, and ANTIOCHUS XI., EPIPHANES (II.), the younger brother of Seleucus; and DEMETRIUS III., EUCÆRUS (94—88), a third brother of Seleucus, who, with Philip, next claimed the sovereignty, which was taken from them by Tigranes (83—69), king of Armenia, at the solicitation of the Syrians; ANTIOCHUS XII., DIONYSUS, a fourth brother of Seleucus, and ANTIOCHUS XIII. (69—65), ASIATICUS. The short-lived prosperity of this dynasty, for it had begun to decline during the reign of SELEUCUS II., 80 years after its foundation, is principally owing to the fatal principle on which it was founded—viz., that of establishing a Græco-Macedonian power in a foreign country, instead of conciliating the attachment of the native populations, and governing them more in accordance with the Eastern method; the consequences were the successive revolts of the natives, the foundation of the independent and hostile kingdoms of Bactria, Parthia, Armenia, Judea, and the ultimate conversion of the small remnant into a Roman province by Cneius Pompeius, 65 B.C.

SELF-DENYING ORDINANCE, a measure carried through parliament in 1645 by the influence of Cromwell and the Independents, with the view of removing Essex and the Presbyterians from the command of the army. It was moved by a fanatic of the name of Zouch Tate, who on the ground that 'there is but one way of ending so many evils, which is, that every one of us freely renounce himself,' proposed, that 'no member of either House shall, during this war, enjoy or execute any office or command, civil or military, and that an ordinance be brought in accordingly.' The ordinance, which was clearly intended to take the executive power out of the hands of the more moderate politicians, and form an army independent of parliament, was the subject of violent and protracted debate, but eventually passed in both Houses, and became law. The consequence was that Essex, Warwick, Manchester, and others gave in their resignation, and the conduct of the war was intrusted to Fairfax; Cromwell, to whom, as a member of the Lower House, the self-denying ordinance extended, as much as to Essex and the rest, had the duration of his commission prolonged by the Commons on account of his invaluable services as a leader of cavalry, and by his brilliant achievements soon surpassed his commander in reputation.

SELIM I., Sultan of Turkey, son of Bajazet II., was born in 1467, dethroned his father by the aid of the Janizaries, 25th April 1512, and ascended the throne. To secure himself in his elevation, he caused his father, brothers, and nephews to be put to death, thus beginning a policy which he pursued inflexibly through the whole of his subsequent career, viz., to destroy without scruple every actual or possible obstacle to the accomplishment of his own ends. Urged on by a devouring appetite for conquest, and by the warlike fanaticism of the Janizaries, he declared war (1514) against Shah Ismail of Persia, and marched eastwards with an army of 250,000 men, massacring on the way 40,000 Shiites. He encountered Ismail at Calderoon, and defeated him with immense loss; but a spirit of disaffection breaking out in his army, he was compelled to content himself with this success, which gave him possession of Diarbekir and Kurdistan. In the following year, he overran Armenia; and leaving his lieutenants to complete this conquest, he marched against the Mameluke Sultan of Egypt, whom he had previously endeavoured to detach from intimate alliance with the Persian monarch. Kansû-ghori, the Egyptian sultan, was totally defeated (1516) at Marjabik by S., and Syria became the prize of the victor; and Kansu's successor, Touman-Bey, was still more unfortunate, his army being almost extirpated (1517) at the battles of Gaza and Rudania. The victorious Turks then entered Cairo without opposition; Touman-Bey and his chief supporters were put to death, and Egypt incorporated with the Ottoman empire. The last lineal descendant of the Abbaside calif, who was then resident in Egypt, transmitted to S. the religious prestige which had devolved upon himself by descent, and at the same time bestowed upon him the title of 'Imaum,' and the standard of the Prophet. In consequence of this gift, the Ottoman sultan became the chief of Islam, as the representative of Mohammed; and the sacred cities of Mecca and Medina, along with the chief Arabian tribes, in consequence acknowledged his supremacy. Thus, in less than four years, S. did more to extend the Ottoman empire than any of his most renowned predecessors during a whole reign. He also laid the foundation of a regular marine, constructed the arsenal of Pera, chastised the insolence of the Janizaries with savage severity, and laboured to ameliorate, by improved institutions, the condition of the various peoples he had conquered. He died 22d September 1520, while planning fresh campaigns against both Persians and Christians. This prince, who in a sense merited his title of *Yavuz* (the Ferocious), was nevertheless a lover and encourager of literature, and even himself cultivated the poetic art. S. was succeeded by his son, Solyman the Magnificent (q. v.).

SELIM III., Sultan of Turkey, the only son of Mustapha III., was born 14th December 1761, and ascended the throne on the death of his uncle, Abdul-Hamid, in 1789. Seeing clearly the causes of the decadence of the empire, and the proper remedies, he inaugurated a policy of renovation and progression; but the war with Russia, in which his newly raised army of 150,000 men was totally defeated, first by the Prince of Coburg, and next by Suwarof, put a stop for a time to his schemes of reform. He was compelled, in 1791, to cede Choczim to Austria, and in the following year, all his possessions beyond the Dniester to Russia. About this time, his good harmony with Napoleon was troubled by the expedition of the French to Egypt, and subsequently by the question of the recognition of the French Empire, but on the whole, S. continued the faithful ally of France; and at every opportunity pursued with ardour his various reforms, establishing cannon-foundries, and organising a body of troops ('the Nizam-Djedit'), armed, clothed, and disciplined in the European fashion; but this last reform stirred up against him (1805) all the fanatic bigotry of his subjects. The priests of Islam even preached revolt in different parts of the empire, and accused their sovereign of despising the holy injunctions of the Koran, so that S. felt compelled to adopt a more cautious policy. At length, a formidable rebellion broke out, and the Nizam-Djedit, who attempted to suppress it, were overpowered, their commander put to death, and the rebels marched into Constantinople, their ranks being swelled at every step by bodies of disaffected Janizaries. All those who had favoured or forwarded the sultan's schemes were seized and put to death, and S. was compelled to issue a decree suppressing the new institutions. But the malignant enmity of the mufti and his coadjutors was not thus to be satisfied, and S. saw himself forced to resign the throne (1807) to his cousin, *Mustapha IV.* (1807—1808).

On the news of this insurrection being conveyed to Mustapha-Bairaktar, the Pasha of Rustchuk, and one of the sultan's chief advisers, this energetic and able soldier marched upon Constantinople, with a view to reinstate S. on the throne, but on his arrival the unfortunate monarch was strangled, and his body cast at the feet of Bairaktar. See BAIRAKTAR. Thus perished S., and with him the first attempt at reformation in Turkey; the effects of which, however, were not wholly lost, for manufactures had begun to flourish, thousands of silk and other looms were now in vigorous operation, a printing press had been established in Scutari, and many other improvements calculated to foster the prosperity and happiness of his subjects had been inaugurated; though these advantages, the natural result of S.'s enlightened patriotism, were neither understood nor appreciated by the great majority of his ignorant and fanatical subjects.

SELI'MNO, a walled, manufacturing town of European Turkey, in Rumili, at the southern base of the Balkan Mountains, 78 miles north of Adrianople. Owing to its far inland position, there is little communication between the town and the coast, and consequently the annual fair held here is

of very great importance. Arms, cloth, and attar of roses are manufactured. Pop. 15,000.

SELJUKS, or SELJUK-TURKS, were an offshoot of the Hoei-He or Hoei-Hu, a collection of tribes of Turkish race, who, being driven southwestward from the Chinese wall, had, in 744 A. D., overwhelmed that Turkish empire of Kiptchak which had given so much annoyance to the Sassanidæ (q. v.) during their reign in Persia. The Hoei-Hu rapidly extended their power from the Caspian Sea as far as the Hoang-ho, and at the time when the S. separated themselves from them, were ruled by a chief named Bigû Khan. Seljuk, from whom the S. derived their name, was the chief of a small tribe which had gained possession of Bokhara and the surrounding country. His sons, attracted by the beauty and fertility of Khorassan, began, about 1027, to migrate to that country, and after some struggles with the Ghiznevide sultans, established themselves in Northern Khorassan, with TOGRUL BEG, the eldest grandson of Seljuk, as their chief, and Nishapur as their capital. Togrul, leaving his brother in Khorassan, set out on his conquering march, subdued Balkh and Khaurezm in 1041, Irak-Ajemi in 1043, subsequently adding to these Kerman and Fars. He then advanced to Bagdad, which he took in 1055, dethroning the last vizier of the Dilemite (see SAMANI) dynasty, and being invested by the reigning calif with the vacant office; after which he completed his conquest of Persia by the reduction of Irak-Arabi and Mosul about 1061. The S. were zealous Mohammedans, and Togrul Beg seems to have been a vigorous promoter of the faith which he professed, for he built numerous mosques, subsidised pious and learned men, and treated the calif—his spiritual chief—with profound respect. After his death in 1063, his nephew, ALP-ARSLAN (q. v.), succeeded to supreme power, and became one of the most renowned monarchs of Asia. His son, MELEK SHAH (1073—1093), the most powerful monarch of this dynasty, added, by means of his generals, Arabia, Asia Minor, Armenia, Syria and Palestine, and Transoxiana to his empire, which now extended from the Hellespont to the borders of Chinese Tartary; and even the ruler of Cashgar acknowledged his authority. This empire, though extensive and ill-compacted, was preserved in the highest order and prosperity by his able minister, the virtuous Nizam-ul-Mulk, under whose firm, just, and wise government the rights of all classes, were maintained, religion promoted, and learning encouraged, till the Persians who had dreaded the conquest of their country by the Turks as the worst of evils, were forced to confess that it had proved the greatest of blessings. In 1092, Melek Shah, lending an ear to the misrepresentations of Nizam-ul-Mulk's enemies, deprived him of his office; and the aged minister was soon afterwards assassinated by one of the followers of Hussun Subah, the chief of the Assassins (q. v.), and the mortal enemy of the good ex-vizier. Hospitals, caravansarais, bridges, roads, and canals attest the zeal with which the commercial interests of the empire were furthered; while the colleges of Bassora, Ispahan, and Herat, the law-college of Bagdad, and the observatory (the first in Asia) of the same city, indicate the care bestowed on the promotion of literature and science. Melek Shah, under whom the empire of the S. had attained the height of its power and splendour, laid a sure foundation for its rapid decline, by subdividing it into a number of separate principalities, all professedly subject to the central state of Iran or Bagdad. The chief of these principalities were: 1. The central state of *the S. of Iran*, whose ruler was the vizier of the calif, and exercised direct authority over Northern and Western Persia to the borders of the Arabian desert. The chief monarchs of this branch were Mohammed Shah, whose generals warred with the Crusaders in Palestine, and Sultan Sanjar, one of the most celebrated of the S. princes, great both in success and misfortune. This branch was annihilated in 1194 by the Shah of Khaurezm. 2. *The S. of Kerman*, who were annihilated in 1191 by the Ghuz Turkomans. 3. *The S. of Iconium*, who ruled over Asia Minor, and whose founder was Soliman, a great-grandson of Seljuk. This branch endured for 224 years—from 1075 to 1299—and during that period was engaged in numerous wars with the Byzantines and with the Crusaders, both of whom learned to dread its power. During its last years, it was tributary to the Mongols; and in 1299, the present Turkish empire rose on the ruins of its power (see OTHMAN). 4. *The S. of Aleppo*, who ruled from 1079 till their extinction in 1114. 5. *The S. of Mosul*, who were speedily supplanted by *attabegs*, or independent governors, of whom Zenghi, and his renowned son, Noureddin (q. v.), were the most celebrated. 6. *The S. of Damascus*, an offshoot (1096) from the Aleppo principality, which lasted till 1155, when it was put an end to by Noureddin. 7. *The S. of Mardein*, who only appear in common history as the allies of the S. of Iconium, Mosul, Aleppo, and Damascus, against the mighty crusading armies of Western Europe. And 8. *The S. of Khaurezm* (*Khiva*), who founded a great empire, including the whole of the country within the Jaxartes, the Bolor Mountains, the Indus, the Sea of Oman, and the Persian Gulf; but the last monarch, Allah-ed-din Mohammed Shah, having wantonly put to death some Mongol merchants who were pursuing their avocations within his dominions, was doomed to destruction by the terrible Genghis Khan (q. v.), who crossed the Sir-Daria, conquered Transoxiana, defeated Mohammed's armies, and drove the Shah himself to take refuge in an island of the Caspian, where he died. The advance of the Mongols was gallantly opposed by Mohammed's celebrated son, Jelal-ed-din, who twice defeated them; but being totally routed (1221), on the west bank of the Indus, by Genghis himself, he plunged his horse into the Indus, and safely reached the opposite bank, none of his enemies daring to follow him. The whole of this extensive empire now fell under Mongol domination.

SELKIRK, ALEXANDER. See JUAN FERNANDEZ.

SE'LKIRK, a Scottish royal burgh, capital of the county of the same name, on an eminence overlooking Ettrick Water and the famous field of Philiphaugh, where General David Leslie defeated Montrose and crushed the cause of King Charles in Scotland, 40 miles by the North British Railway south-south-east of Edinburgh. The town-hall, with a spire 110 feet high, and the monuments to Sir Walter Scott and to Mungo Park, are the principal architectural features. S. has very large woollen mills. Tweeds, hosiery, and blankets are the chief articles of manufacture. Pop. (1861) 3695.

S. commands a splendid view across the valley or haugh in which the Ettrick and Yarrow meet. It is within a few miles of many of the most famous localities in Scotland, and is a favourite starting-point for tourists desirous of exploring the 'Scott' country (Melrose, Abbotsford, Dryburgh, &c.), the 'Forest,' the Yarrow, and St Mary's Loch. From Ettrick, a large body of fighting men went to join King James in his fatal march to Flodden. Upwards of a hundred were from S. alone, of whom only four returned, but these proudly bore a standard taken from the enemy on that occasion. The manufacture of 'single-soled shoon' long flourished

here, and the 'Souters of Selkirk' are commemorated in song and story.

SELKIRKSHIRE, in ancient times called Ettrick Forest, is bounded by the counties of Midlothian, Roxburgh, Dumfries, and Peebles, on the N., E., S., and W. respectively. It extends in length from north to south about 28 miles, and from east to west 16 to 18 miles, and consists mainly of the two parallel valleys through which flow the rivers Ettrick and Yarrow. Its area is 266 sq. m., or 170,240 acres. S. contains three entire parishes, and parts of other seven. It is in a great measure a pastoral county, and some of the hills are of considerable altitude, being upwards of 2000 feet in height. The hills are rounded at the top instead of peaked, and are covered generally with grass, affording excellent pasturage, but in some places with heather. The arable land, situated from nearly 300 to 800 feet above sea-level, and bearing the proportion of about one-eighth of the area, is, in general, of a light soil, and produces the ordinary crops in abundance. Besides the Ettrick and Yarrow, the Tweed, Gala, and Cawder flow through parts of the county. The banks of several of these are beautifully wooded; but the extensive woods from which the county originally took its name of the Forest, have disappeared. According to the agricultural statistics taken in the year 1858, the number of occupants of land was 172, and the acreage under grass and hay was 6012 acres; and under crops, 14,411—of which there were in wheat 261 acres, averaging 29 bushels, 1 peck per acre; 949 acres of barley, averaging 36 bushels; 4162 acres of oats, averaging 38 bushels; 29 acres of beans and pease, averaging 17 bushels, 1 peck; turnips, 2624 acres, averaging 16 tons, 15 cwt.; and 222 acres of potatoes, averaging 2 tons, 7 cwt. The above enumeration shews an average of produce considerably above most of the other counties, except potatoes, which is the 7th lowest. Of horses, there were 763; of cattle, 2449; of sheep, 145,732; of swine, 474—total stock, 149,418. The old valued rent was £6692. The new valuation, including the burgh, is rather more than £70,000. This county contains some interesting historical scenes, among which is the field of Philiphaugh, where the great Marquis of Montrose was defeated by the Covenanters under General Leslie. Oakwood Castle, in ruins, was the residence of the famous wizard Michael Scott; and Newark, also in ruins, was the residence of Anne, Duchess of Buccleuch, where the *Lay of the Last Minstrel* is represented by Scott as having been sung. S. is pretty well appointed for roads, and the Hawick line of the North British Railway runs for a short distance along its border, from which, at Galashiels, there is a branch to Selkirk. There are 15 places of worship, 5 of which belong to the Establishment, 5 to the Free Church, and the rest to other dissenters. There is no coal, or lime, or sandstone. The Douglas family, four centuries ago, were the principal proprietors. The Duke of Buccleuch now holds about two-thirds of it. The population in 1861 was 10,449, the inhabited houses 1468. S. returns one member to parliament.

SE'LTERS WATER (commonly but incorrectly written *Seltzer Water*), takes its name from the village of Lower Selters near Limburg, in the duchy of Nassau, where several springs united, in one basin, yield 5000 cubic feet an hour of this sparkling and effervescing mineral water. Its chief ingredients are carbonic acid, carbonate of soda, and common salt. It acts as a mild stimulant of the mucous membranes and as a diuretic; and is applied in chronic disorders of the digestive, respiratory, and urinary organs. It is much recommended as a beverage, either alone or with sugar, to those suffering from liver complaint, and in hot climates and seasons. More than 1½ millions of jars or bottles of this famous water are exported yearly to all quarters of the world, affording to the state a revenue of above £6000. The spring was discovered early in the 16th c., but was at first so little prized, that in the middle of the 18th c. it was rented for 4*s*. The water is little drunk at the spring. Artificial Selters Water is extensively manufactured both on a large scale and for domestic use. See AËRATED WATERS.

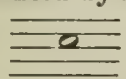
SE'MAPHORE (from *sēma*, a sign, and *pherō*, I bear) was the name applied to the system of telegraphy in use before the application of the electric current. Semaphores were first established by the French in 1794, as a plan for conveying intelligence from the capital to the armies on the frontier. In the following year, Lord George Murray introduced them in England; and by their means the Board of Admiralty were placed within a few minutes of Deal, Portsmouth, or Plymouth. These semaphores consisted of towers built at intervals of from 5 to 10 miles, on commanding sites. On the top of each tower was the telegraph apparatus, which at first

Semaphore.

comprised 6 shutters arranged in 2 frames, by the opening and shutting of which, in various combinations, 63 distinct signals could be formed. In 1816, Sir Home Popham substituted a mast with 2 arms, similar to many of the present railway signals. The arms were worked from within the tower by winches in the look-out room, where a powerful telescope in either direction constantly commanded the mast of the next station. If a fog set in at any point on the route, the message was delayed; otherwise, when a sharp look-out was kept, the transmission was very rapid. For instance, the hour of one by Greenwich time was always communicated to Portsmouth when the ball fell at Greenwich; the semaphores were ready for the message, and it commonly passed from London to Portsmouth and the acknowledgment back to London within three-quarters of a minute. Each station was in the charge of a naval officer—usually a lieutenant—with one or two men under him. To save the cost of this establishment, the Deal and Plymouth lines fell into disuse soon after the peace of 1815; and the superior advantages of the electric telegraph being incontestable, the Portsmouth line sent its last message on the 31st December 1847, and, on land at least, the semaphore closed its career of usefulness for ever. In calm weather, when flags will not extend, semaphores are employed on board ship as a means of signalling from vessel to vessel, or to the shore; in such a case, the post containing the arms is movable, and can be readily shipped or unshipped near the stern. See also SIGNAL.

SE'MÉ, in Heraldry. When a charge is repeated an indefinite number of times so as to produce the

appearance of a pattern, the term *semé* (sometimes *aspersed* or *powdered*) is applied to it. When a field is semé, it is treated as if it were cut out of a larger extent of surface, some of the charges being divided by the outline of the shield. The term *crusilly* denotes semé of cross crosslets, and *billetty* semé of billets.



Semé.

SEMECA'RPUS, a genus of trees of the natural order *Anacardiaceæ*. The MARKING NUT of India is *S. anacardium*, a tree 50 feet high, growing on mountains. The swollen receptacle of the flower becomes a succulent fruit, eatable when roasted, but astringent and acrid when raw. On the receptacle is seated the nut, which is heart-shaped and black, consisting of a kernel—not unwholesome, although rarely eaten—surrounded by two skins, between which is a black acrid juice. This juice is used in medicine as an external application to heal rheumatism, &c. It is also in general use in India for marking cotton cloth; and the colour is improved, and running prevented, by the addition of a little quicklime and water. The wood of the tree contains so much acrid juice that it is dangerous to work upon.

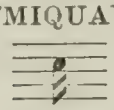
SE'MELE. See BACCHUS.

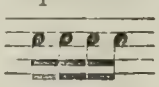
SE'MENCINE, SEMEN CINÆ, AND SEMEN CONTRA. See ARTEMISIA.

SEME'NDRIA, a frontier fortress of the principality of Servia (q. v.), stands amid romantic scenery on the right bank of the Danube, 28 miles south-east of Belgrade. The inhabitants, about 8000 in number, are employed principally in the wine-culture, in breeding hogs, and in general trade. It was at one time the seat of the Servian kings; and it has been frequently stormed by the nations who have contended for the Danube from the middle ages to the present century.

SE'MIBREVE, in Music, a note of half the duration of the breve of old ecclesiastical music, but the longest note in use in modern music. It is represented by a character circular or elliptical in form  and is adopted as the integer or measure-note, the other notes—minim, crotchet, quaver, &c.—being proportional parts of it.

SEMI-DEMI-SEMIQUAVER, a musical note, of which 8 are equivalent to a quaver, 16 to a minim, and 32 to a semibreve. It is represented thus,  or in groups thus, 





SE'MINOLES, a tribe of American Indians, originally a vagrant branch of the Creeks, whose name, Seminole, signifies wild or reckless. In 1705, they aided in driving the Appalaches from Florida; and in 1817, they joined with the Creeks and some negroes who had taken refuge with them, ravaged the white settlements in Georgia, plundering plantations, and carrying off slaves, whom they refused to surrender. General Jackson, sent to punish them, took at the same time several Spanish forts, and hastened the negotiations which ended in the cession of Florida to the United States. At this cession in 1823, the S. engaged to retire into the interior, and not molest the settlers; but as the negroes continued to take refuge with them, a treaty was made with some of the chiefs, in 1832, for the removal of the whole tribe west of the Mississippi. This treaty was repudiated by the tribe, at the instigation of Osceola (q. v.), one of their chiefs; and a war commenced against a handful of savages, which lasted eight years, and cost thousands of lives, and ten millions of dollars. In the end, the remains of the tribe were removed to the Indian Territory on the borders of Arkansas.

SEMIPALATI'NSK, an extensive Russian territory in Siberia, is bounded on the E. and S. by Tomsk, the Chinese Empire, and Turkestan. Area, 178,128 sq. m.; pop. 217,451. It is separated from Turkestan on the south by the Alexandrian Mountains in lat. 42° 30′ N., and it is traversed by several other mountain chains. The chief rivers are the Irtish, Ili, and Chui; and among the lakes are those of Issik-Kul, Ala-Kul, and Balkash. The country abounds in pasturage, and cattle form almost the sole wealth of the inhabitants, although the precious metals, together with lead and copper, are found. Steamers ply on the great rivers and lakes. In 1867 a part of Semipalatinsk, situated south of the Tarbagatai chain, was included in the government of Turkestan.—Semipalatinsk, the capital, stands on the left bank of the Irtish, in lat. about 50° 15′ N. Pop. about 7000.

SEMI-PELA'GIANISM, a modification, as the name implies, of the doctrine of the Pelagians as to the powers of the human will, and as to the effects to be attributed to the action of the supernatural grace of God, and of the divine decree for the predestination of the elect. The Pelagians (q. v.), discarding altogether the doctrine of the fall of Adam, and the idea that the powers of the human will had been weakened through original sin, taught that man, without any supernatural gift from God, is able, by his own natural powers, to fulfil the entire law, and to do every act which is necessary for the attainment of eternal life. The condemnation of this doctrine by the several councils held in the early part of the 5th c. is capable of various constructions, and has been urged by some to the extreme of denying altogether the liberty of man, and converting the human will into a merely passive instrument, whether of divine grace upon the one hand, or of sinful concupiscence upon the other. The writings of St Augustine on this controversy have been differently construed by the different Christian communions (see PELAGIANS); and the same diversity of opinion existed in his own day. Among those who, dissenting from the extreme view of Pelagius, at the same time did not go to the full length of the Augustinian writings in opposition to Pelagius, were some monks of the southern provinces of Gaul, and especially of Marseille, whence their school was called Massilian, from the Latin name (*Massilia*) of that city. Of these leaders, the chief was a priest named Cassian, who had been a deacon at Constantinople. Of the system which he propounded, without going into the details, although many of them are exceedingly curious and interesting, it will be enough to say that it upheld the sufficiency of man's natural powers only so far as regards the first act of conversion to God and the initial act of man's repentance for sin. Every man naturally possesses the capability of beginning the work of self-conversion; but for all ulterior acts, as well as for the completion of justification, the assistance of God's grace is indispensable. The Semi-Pelagian doctrine is often confounded with that of the Molinistic (see MOLINA) school of Roman Catholic theology; but there is one essential difference, viz., that the latter persistently maintain the necessity of grace for all supernatural acts, even for the beginning of conversion, although they are generally represented as

agreeing with the Semi-Pelagians as to the mode of explaining the freedom of the human will acting under the influence of divine grace. The chief writers in the controversy were Prosper, Hilary, and Fulgentius; and the question was referred to Celestine, Bishop of Rome in 431. It continued, however, to be agitated in the West for a considerable time. Faustus, Bishop of Riez, towards the end of the 5th c., revived the error, and it was condemned in a council held at Arles in 475, and still later in a synod (the second) held at Orange (Arausio) in 525, and again in the third council of Valence in 530.

SEMIPLE'NA PROBA'TIO, in Scotch Law, is that kind of half-proof, half-suspicion which was usually given in cases of affiliating a bastard, as well as in a few other cases. It was a species of *primâ facie* evidence; and when considered by the court sufficient, it was eked out by the oath of the party, called an Oath in Supplement (q. v.). The practical effect of the admission of parties as witnesses, under 16 Vict. c. 20, has been to do away with Oaths in Supplement, the parties being usually the principal witnesses, and the court deciding from a consideration of the balance of credibility between them.

SE'MIQUAVER, a musical note, represented thus,  or in groups thus,  equivalent in value to $\frac{1}{2}$ of a quaver, $\frac{1}{4}$ of a crotchet, $\frac{1}{8}$ of a minim, or $\frac{1}{16}$ of a semibreve.

SEMI-QUI'ETISM, a form of mystical asceticism which, while it adopts the theoretical principle, that the most perfect state of the soul is that of passive contemplation, and denies, in certain conditions of the soul, the necessity of prayer or other active manifestations of virtue, yet maintains the incompatibility of this passive contemplation with any external sinful or sensual action. The Semi-Quietists thus differed from the grosser sectaries referred to under QUIETISM.

SEMI'RAMIS. See ASSYRIA.

SEMITIC. See SHEMITIC.

SE'MITONE, in Music. The name given to the smaller intervals in the diatonic scale, as E F or B C, in which the ratio is as 15 to 16.—In the pianoforte, the interval between any two notes between which no other note is interposed, as C to C♯ or B♭ to B, is a semitone.

SEMLER, JOHANN SALOMO, one of the most influential German theologians of the 18th c., was born, 18th December 1725, at Saalfeld, where his father was archdeacon, educated at Halle, and in 1749 went to Coburg as professor at the gymnasium. In 1751, he was appointed a Professor of Theology at Halle, where he taught with great success; and six years later, became director of the theological seminary there. He died 14th March 1791. S. was, in the early part of his student-career, somewhat of a Pietist, but the prelections of Sigm. Jak. Baumgarten may be said to have revolutionised his religious convictions, and swung him round to rationalism, of which he was the first systematic exponent. S.'s rationalism, however, was always moderate in *degree*, though definite enough in *kind*. As a thinker, he was deficient in philosophical consistency and breadth of view; and as a writer, he possessed no literary skill or grace; but his works are valuable for the spirit of historical criticism by which they are pervaded. The principal are: *Apparatus ad liberalem Veteris Testamenti Interpretationem* (Halle, 1773), *Abhandlung von der Untersuchung des Kanons* (4 vols., Halle, 1771—1775), *De Dæmoniacis* (Halle, 1760), *Umständliche Untersuchung der Daemonischen Laute* (Halle, 1762), *Versuch einer Biblischen Daemonologie* (Halle, 1776), *Selecta Capita Historiæ Ecclesiasticæ* (3 vols., Halle, 1767—1769), *Commentationes Historicæ de Antiquo Christianorum Statu* (2 vols., Halle, 1771—1772), *Versuch Christlicher Jahrbücher oder ausführliche Tabellen über die Kirchengeschichte bis aufs Jahr.* 1500 (2 vols., Halle, 1783—1786), *Observationes novæ, quibus Historia Christianorum usque ad Constantinum Magnum illustratur* (Halle, 1784).—See his *Lebensbeschreibung von ihm selbst verfasst* (Halle, 1781—1782), Wolf, *Ueber Semler's letzte Lebenstage* (Halle, 1791), H. Schmid, *Theologie Semler's* (Nordlingen, 1858), and Tholuck in his *Vermischt Schriften.*

SEMLI'N, a frontier town of Austria, in the Military Frontier, stands on a tongue of land at the junction of the Save and Danube, on the right bank of the latter, opposite Belgrade. Within recent years, the town has been much improved, though even yet a suburb consisting of mud huts thatched with reeds stretches along the Danube. The only noteworthy edifices are the churches, the German theatre, and the Lazaretto (*Contumaz*), the chief quarantine station in the whole of the Military Frontier. At this institution, travellers crossing from Turkey are compelled to remain a greater or less time—sometimes 40 days—in proportion to the violence and proximity of the plague. The reason why the principal Lazaretto is here is, that S. is the great seat of the Turco-Austrian transit-trade, and the principal ferry for passengers from Christendom to the land of the Moslem. Pop. 9900.—For a graphic notice of S., see Kinglake's *Eothen.*

SEMMERING, a mountain on the borders of Styria and Austria, and 44 English miles south-west-by-west from Vienna, is 4416 feet above the level of the sea. The Vienna, Grätz, and Trieste Railway has been carried across this mountain by a series of ingenious engineering contrivances. See GLOGGNITZ.

SEMNOPITHE'CUS, a genus of monkeys, natives of the East, having a very long, slender, powerfully muscular, although not prehensile tail. The canine teeth are long, but the molar teeth are more tuberculous than in Gibbons (q. v.) and other allied monkeys, indicating a greater aptitude for vegetable food. With this the structure of the stomach corresponds, which is very remarkable, and different from that of all other animals; consisting of a cardiac pouch, slightly bifid at the extremity; a very wide middle portion, formed of numerous pouches or sacs; and a very long canal, furnished with sacs at its commencement, but simple towards its termination. Professor Owen has been careful, however, to point out that these three portions do not correspond to any of the parts of the stomach of a ruminant animal, not exhibiting any such diversities in their internal surface. The species are numerous. The Entellus (q. v.) Monkey is one of them. Another is the Negro Monkey (*S. Maurus*) of Java, remarkable for its jet-black colour and long silky hair.

SEMOLI'NA (Semola or Semoule), an article of food much used in France and Italy, and to a small extent in Britain, and other countries. It consists of particles of wheat varying in size from grains of sand to small millet. Only the hard-grained wheats of Spain, Odessa, and Southern Italy are adapted for making it; these hard wheats are not easily reduced to flour, and small particles escape being crushed by the mill-stones, and will not pass through the sieves—these constitute semolina. In France, more attention is paid to this article than in any other country; and as it fetches a higher price than flour, the skilful

miller so adjusts his mill-stones as to produce a considerable quantity. The granules of semolina are of various sizes, and they are carefully separated by sieves, the openings of which are from fine to coarse. A favourite kind of bread made of the coarser kinds of semolina—the semoule of the French—is sold in Paris under the name of *gruau*. In Italy, it is used in making polenta, in common with maize, meal, and millet; and in Britain it is used for puddings.

SE'MPACH, a small town of Switzerland, in the canton of Lucerne, and 9 miles by railway north-west of the town of that name, stands on the east shore of the lake of Sempach. It is surrounded with walls, now in a ruinous condition, has a population of a little over 1000, and was one of the outposts of the confederate cantons against their Swabian and Austrian assailants in the 14th century. Under the walls of S. took place the second great conflict of the confederated Swiss cantons with Austria. Leopold's army of 4000 horse and 1400 foot arrived before S. on the 9th July 1396, and found itself unexpectedly opposed by the confederated Swiss to the number of 1300. The nature of the ground being unfitted for the action of cavalry, the knights dismounted, and formed themselves into a solid and compact body, which was at once charged by the Lucerners; but the wall of steel was impenetrable, and not a man of the Austrians was even wounded, while 60 of the bravest of Lucerne with their landamman fell. The mountaineers were beginning to despair of making an impression on their apparently invulnerable opponents, when Arnold von Winkelried, a knight of Unterwalden, seized with a noble inspiration, rushed forward, grasped with outstretched arms as many pikes as he could reach, buried them in his bosom, and bore them by his weight to the earth. His companions rushed over his body into the breach thus made, slaughtered the armour-encumbered knights like sheep, and threw the remainder into the utmost confusion and dismay. The conflict continued in an irregular manner for some time longer, but the result was a decisive victory for the Swiss, who had lost only 200 men; while the loss of the Austrians was ten times as great, including 600 counts, barons, and knights. The body of Duke Leopold, who had throughout displayed the most obstinate valour, was found next day buried among a heap of slain. The anniversary of this great victory is still celebrated by prayer and thanksgiving on the field of battle.

SEMPERVI'VUM. See HOUSE-LEEK.

SENATE. See ROME.

SENA'TUS ACADE'MICUS, one of the governing bodies in the Scottish universities, consisting of the Principal and Professors. It is charged with the superintendence and regulation of discipline, and the administration of the university property and revenues, which last function, since the Universities Scotland Act of 1858, the Senatus exercises subject to the control and review of the University Court. Degrees are conferred by the Senatus through the Chancellor or Vice-chancellor. The Principal is president, and besides his deliberative vote, has a casting vote. In his absence, the senior professor present acts as chairman, who has also a double vote. One-third of the Senatus is required to form a quorum.

SENDOMIR or SANDOMIR MOUNTAINS. See RADOM.

SE'NECA, M. ANNÆUS, the rhetorician, was born at Corduba (Cordova) in Spain. The time of his birth is doubtful, probably about 61 B. C. He seems to have been in Rome during the early period of the power of Augustus. He was rich, belonged to the equestrian order, and enjoyed the friendship of many distinguished Romans. From Rome he returned to Spain, where he married Helvia, and had by her three sons. The time of his death is uncertain; but he probably lived till the close of the reign of Tiberius, and died in Rome or Italy. His extant works are *Controversiarum Libri X.*, and *Suasoriarum Liber*, neither of which is complete. They are elaborately rhetorical in style, but do little to support the fame of their author, who is more remembered for his prodigious memory than for anything else.

SENECA, L. ANNÆUS, son of the preceding, and a celebrated philosopher, was also born at Corduba, a few years B.C. When a child, he was brought by his father to Rome, where he was initiated in the study of eloquence. He cared more, however, for philosophy, in which his first teacher was the Pythagorean Sotion, whom he afterwards left to follow Attalus the Stoic. He travelled in Greece and Egypt; and, in obedience to his father's wishes, he pleaded in courts of law; but notwithstanding his forensic triumphs, he left the bar from fear of Caligula's jealousy. On entering into public life, he filled the office of quæstor, and had already risen high in the favour of the Emperor Claudius, when he was accused of an adulterous connection with Julia, the daughter of Germanicus, and wife of Vinicius. He was exiled to Corsica, where he remained for eight years, deriving from philosophy what consolation he could, while incessantly complaining with a by no means philosophic querulousness, and appealing to the emperor for pardon. When Claudius married his second wife, Agrippina, S. was recalled by her influence, raised to the prætorship, and appointed instructor of her son Nero. On the death of his governor and military tutor, Burrus, Nero gave way to his depraved passions with a force which S. could not control. All his influence over his pupil was lost, but he profited by his extravagant bounty to such a degree that his accumulated wealth amounted to 300,000 sestertia, or to £2,421,870 of our money. Nero soon began to look with envious eyes on this fortune; and S., to avert dangerous consequences, offered, with much tact, to refund to the emperor his gifts, and begged leave to retire on a small allowance. This Nero declined; and S., under pretence of illness, shut himself up, and refused to appear in public. Nero then attempted to have him poisoned, but failed. A short time afterwards, Antonius Natalis, when on his trial for participating in the conspiracy of Piso, implicated S. as one of the conspirators. This was quite enough to fix S.'s guilt. He was sentenced to put himself to death. His wife, Paullina, declared her resolution to die with him, and, in spite of his remonstrances, accompanied him into the bath in which, according to his own choice, he was to be bled to death. The emperor, however, would not allow Paullina to die, but removed her from her husband, who gradually expired, 65 A.D. S.'s extant writings are mainly on moral subjects, and consist of Epistles, and of treatises on Anger, Consolation, Providence, Tranquillity of Mind, Philosophical Constancy, Clemency, The Shortness of Life, A Happy Life, Philosophical Retirement, and Benefits. He also speculated on physical phenomena, and wrote seven books entitled *Quæstiones Naturales*, in which he is thought to have anticipated some notions regarded as principles in modern physics. Ten tragedies, ascribed to him by Quintilian, and generally included in editions of his works, have also come down to us; but whether he is really their author remains still a dubious and debated point. Some allege that they were the

work of his father, Seneca the rhetorician; some that they must be attributed to another Seneca. They were not intended, and are certainly not adapted, for the stage. They are overcharged with declamation; and, if rich in moral sentiments, are wanting in dramatic life. Of his genuine prose writings, modern opinion takes a divided view; some critics praising his practical sagacity, others finding him wanting in speculative reach. It is perhaps a significant fact, that he is admired by French scholars, and disparaged by German. One of the best editions of the prose works is the Bipontine 1809; of the tragedies, that of Bothe, 1819.

SENECA LAKE, one of a range of narrow lakes in the western part of the state of New York, U. S. It is 37 miles from north to south, and from 2 to 4 miles in width, 447 feet above the Atlantic, 630 feet deep, and was never known to be frozen over until March 1856. It is navigated by steamboats from its head to the pretty village of Geneva at its mouth, and empties itself by the Seneca and Oswego rivers into Lake Ontario. It takes its name from the Seneca Indians, one of the Six Nations.

SENE'CIO, a genus of plants of the natural order *Compositæ*, suborder *Corymbiferæ*, having a hairy pappus, a naked receptacle, and a cylindrical involucre of linear equal scales, with a few smaller scales at their base. The species are very numerous; annual, perennial, and half-shrubby plants, natives chiefly of the temperate and cold parts of the world, the half-shrubby species being from the warmer latitudes. Eleven species are reckoned as British, and commonly known as Groundsel (q. v.) and Ragwort (q. v.). *S. Saracenicus*, probably not a true native of Britain, but introduced in the middle ages, has undivided lanceolate leaves, and was once in repute as a vulnerary. The FIREWEED of North America is *S. hieracifolius*. It receives its popular name from its appearing abundantly wherever a part of the forest has been consumed by fire. Many species of S. have a strong disagreeable smell. A few are rather ornamental as flowers.

SENE'FFE, or SENEF, a town in the province of Hainault, Belgium, about 11 miles north-west of Charleroi, has a pop. of between 3000 and 4000, and is the centre of a district in which manufactures of pottery and glass are extensively carried on. S., however, is chiefly notable for its proximity to the battlefield on which William of Orange (III. of England), at the head of the forces of the coalition against France, was defeated, after a bloody contest, by the Great Condé, 11th August 1674. In William's army there were four lieutenants—Montecuculi (q. v.), Duke Charles of Lorraine, the Prince of Waldeck, and the Prince of Vaudemont, the first three of whom subsequently attained prominence as military commanders. Of the allied forces of 60,000 men, the Dutch lost from 5000 to 6000 men, the Spaniards 3000, and the Imperialists 600; while the French army, which entered into the conflict 30,000 strong, could scarcely muster 20,000 after their victory.—Under the walls of S., Moreau, in 1794, defeated the Austrians.

SE'NEGA or SNAKE ROOT is the dried root of *Polygala Senega*. The following are its characters: 'A knobby root-stock, with a branched tap-root of about the thickness of a quill, twisted and keeled; bark, yellowish-brown, sweetish, afterwards pungent, causing salivation; interior, woody, tasteless, inert.' Senega is a powerful and trustworthy stimulating expectorant, and may be advantageously prescribed in the advanced stages of chronic bronchitis and pneumonia, especially when occurring in aged or very debilitated patients. It is also a valuable remedy in prolonged hooping-cough, and in the latter stages of croup and of bronchitis in young children. The preparations are the Infusion and the Tincture; the average dose of the former being an ounce and a half, of the latter a drachm. For children, the powdered root in doses of ten grains is the best form. See POLYGALA.

SENEGA'L (called by the natives *Senaga*), a large river in Western Africa, rises in Mount Cooro, in lat. 10° 30′ N., long. 10° 40′ W., flows first north-west and then west, and falls into the Atlantic after a course of 1000 miles, for the last 740 of which it is navigable for flat-bottomed boats. Here and there, throughout the whole course, the navigation is interrupted by cataracts, shoals, and rocks. In the lower course, the river forms numerous, large, cultivated, and very fertile islands, and its banks are green and productive, and in part clothed with wood. The entrance is difficult on account of breakers and a bar which, in the dry season, is covered by only 8 to 9 feet of water.

SENEGAL, the name of the French possessions on the river Senegal in Senegambia (q. v.).

SENEGA'MBIA, a large maritime tract of country in Western Africa, in lat. about 10°—18° N., long. about 4°—17° 30′ E., is bounded on the N. and W. by the Sahara and Sudan, on the S. by the colony of Sierra Leone, and on the W. by the Atlantic. Area about 400,000 sq. m.; pop. estimated at about 9,000,000. The country takes its name from its two principal rivers, the Senegal and the Gambia. Between these two rivers, which are 250 miles apart, there are no water-courses of any importance, and from the Gambia south to the frontier of Sierra Leone, the only considerable stream is the Rio Grande. The coast is deeply indented by arms of the sea, which resemble the estuaries of rivers. The country forms the western and northern declivity of the plateau of Kong, and part of it is still unexplored. The soil is of two kinds, that of the coasts and that of the interior: the former consisting in part of low flat alluvial plains, and partly of an undulating country, which broadens toward the north, until, on the northern frontier, it merges into the Sahara; while the plateau of the interior rises from the coast plains in mountainous terraces, until it loses itself in the Kong Mountains. Its loftiest elevations are only about 3280 feet high. S. is divided into three districts—High, Middle, and Low Senegambia. The first comprises the country to the north of the Senegal, and is inhabited by Moors, who, of course, profess Islamism. Middle S. comprises the countries bordering the Senegal, having an area of 1350 sq. m., and is inhabited by Negroes, who divide themselves into numerous tribes. Of this tract, the climate is extremely hot, and is unhealthy in the marshy districts. The soil is generally fertile, and yields the crops usually produced in the hot regions of Africa. Low S. comprises the countries bordering the Gambia, and extends south to Nunez. Of the coast-regions of S., France possesses on the banks and around the estuary of the Senegal about 1440 sq. m. of territory; the Portuguese, a tract of 35,437 sq. m., on and around the estuary of the Rio Grande; and the English some little territory on the Gambia.

SE'NESCHAL (Teuton. *sene-scalc*, senior servant?), in the origin of the office, probably an attendant of the servile class who had the superintendence of the household of the Frankish kings. In the course of time, however, the seneschalship rose to be a position of dignity, held no longer by persons of servile race, but by military commanders, who were also invested with judicial authority. The

lieutenants of the great feudatories often took the title of seneschal. A similar office in England and Scotland was designated steward, but is rendered into Latin as *senescallus*.

SENIOR, NASSAU WILLIAM, political economist, born 1790, eldest son of Rev. J. R. Senior, vicar of Durnford, Wilts, was educated at Eton, and Magdalen College, Oxford, where he graduated in 1811, taking a distinguished first-class in classics. In 1819, he was called to the bar at Lincoln's Inn. In 1825, he was elected to the professorship of Political Economy at Oxford, founded by the late Henry Drummond, M.P. He held it for the statutory term of five years, and was succeeded by Mr Whately, afterwards Archbishop of Dublin. In 1832, the enormous evils of the poor-law administration in England led to the appointment of a Commission of Inquiry. S. was one of the commissioners; and the portion of the Report in which the abuses of the existing system were detailed, was drawn up by him. This Report encouraged the Whig government to bring in the Poor-law Amendment Act of 1834. See POOR AND POOR LAWS. In 1836, he received the appointment of Master in Chancery; and in 1847, was re-elected to his former professorship for another term of five years. More recently, he was nominated one of the commissioners of National Education, under the presidency of the late Duke of Newcastle. His publications, which are numerous, comprise various excellent treatises on political economy, some of which were delivered in the form of lectures at Oxford, and several pamphlets on social and political questions. He also contributed numerous articles to the *Edinburgh Review*, and other leading periodicals. He has left some interesting journals of his visits to Turkey and Greece, and observations on the political and social condition of these countries. His *Essays on Fiction*, contributed to the chief reviews between the years 1821 and 1857, and republished in 1864, relate principally to the novels of Scott, Bulwer Lytton, and Thackeray. He analyses the plots, and classifies the characters of the Waverley novels with curious felicity, and devotes a masterly essay to Thackeray, whom he regards as the greatest novelist of his day. The intellect of S. was clear and penetrating, and the perspicuity of his style made him an able expositor of the truths of political and social science. His article on 'Political Economy' in the *Encyclopædia Metropolitana*, and his remarks on some definitions in this science, published in the appendix to Dr Whately's treatise on *Logic*, may be consulted with advantage. He died June 4, 1864.

SENLIS, a very ancient town of France, dep. of Oise, 33 miles north-north-east of Paris. Its older portion is surrounded by walls, flanked with 16 towers, which are all that remain out of the 28 towers of early times. The cathedral, a small edifice, is a beautiful example of early Gothic. Manufactures of cloth, lace, and thread are actively carried on. Pop. (1862) 5831.

SENNA is one of the most important purgatives contained in our Materia Medica. Two sorts of senna are recognised in the Pharmacopœia—viz., Alexandrian senna and Tinnevelly senna. The Alexandrian senna leaves are chiefly obtained from *Cassia lanceolata*, while the Tinnevelly senna leaves are yielded by *Cassia elongata*. *Alexandrian senna* is chiefly grown in Nubia and Upper Egypt, and is imported in large bales from Alexandria. It is apt to be adulterated largely with the flowers, pods, and leaves of *Cynanchum arghel* and *Tephrosia apollinea*. *Tinnevelly* or *East Indian senna* in odour and taste entirely resembles Alexandrian senna. The leaflets are, however, 'about two inches long, lanceolate, acute, unequally oblique at the base, flexible, entire, green, without any admixture.'

Senna is, as Dr Christison observes in his *Dispensatory*, 'so certain, so manageable, and so convenient a purgative, that few remedies of its class are held in equal estimation. In point of energy, it holds a middle place between the mild laxatives and drastic cathartics. It acts chiefly on the small intestines, increasing their mucous secretion, as well as their peristaltic motion, and producing loose brown evacuations.' The drawbacks to its more universal administration are its disagreeable taste, and its tendency to produce nausea, griping, and flatulence; the means of correcting which are subsequently noticed. The only circumstance positively contra-indicating its employment is an inflammatory state of the intestinal mucous membrane. Although senna has been frequently submitted to chemical analysis, its active principle is not known; but whatever the cathartic principle may be, it is obviously absorbed into the circulation before it begins to operate, since this drug imparts a purgative property to the milk of nurses.

The following are the most important preparations of this medicine:

1. *Infusion of Senna*, which is obtained by infusing for one hour, and then straining, half an ounce of senna and half a drachm of sliced ginger in half a pint of boiling water. The taste of this infusion is much concealed by the addition of some black tea, or what Neligan finds 'still better, coffee, and it may be sweetened with sugar, and milk added; it is in this way readily taken by children.' The addition of neutral laxative salts checks the griping, which is often caused by senna alone, and at the same time increases its activity. The ordinary *Black Draught* is commonly prepared by adding one ounce of sulphate of magnesia to four ounces of infusion of senna. Two or three ounces of this mixture, to which a drachm each of the tinctures of senna and of cardamoms may be added, usually act as a very useful aperient.

2. *Tincture of Senna*, composed of senna, raisins, caraway seeds, and coriander seeds macerated in proof-spirit, and formerly known as *Elixir Salutis*, or *The Elixir of Health*, is seldom given alone. Christison recommends a mixture of an ounce of the tincture of senna with an ounce and a half of sulphate of magnesia, dissolved in four ounces of water, and as much infusion of roses. 'A wine-glassful of this given every hour seldom fails to act with energy, and without sickness or tormina, and is an excellent combination for most febrile disorders.' The tincture is, however, most commonly prescribed in doses of one or two drachms, as an adjunct to other cathartic mixtures, to correct their griping properties.

3. *Confection of Senna*, commonly known as *Lenitive Electuary*, is a pulpy mixture of powdered senna with powdered coriander seeds, figs, tamarinds, cassia pulp, prunes, extract of liquorice and sugar; all of which substances are, under certain specified conditions, combined by the action of boiling water. When properly prepared, which is often not the case, it forms a mild aperient, well suited for persons suffering from piles.

In the above preparations, it is immaterial whether Alexandrian or East Indian senna is employed.

The senna leaves of commerce and of medicine are the produce of several species of *Cassia* (q. v.), natives of India, Arabia, Syria, and the north of Africa. *Cassia obovata* is a perennial herbaceous

plant 1—2 feet high, having smooth leaves, six or seven pair of obovate obtuse leaflets, racemes of yellow flowers, and curved, compressed pods, with an interrupted ridge along the middle of each valve. It is found in Egypt and Nubia, and is now also cultivated in Italy, Spain, the West Indies, &c.—*C. acutifolia* is a half-shrubby plant, about two feet high, with racemes of yellow flowers, lanceolate acute leaves, and flat elliptical pods, somewhat swollen by the seeds. It grows in the deserts near Assouan, and the leaves are collected by the Arabs, and carried by merchants to Cairo for sale.—*C. elongata* is an annual with erect, smooth stem; narrow leaves, with 4—8 pair of lanceolate leaflets, which are rather downy beneath; racemes of yellow flowers; and oblong pods, quite straight, rounded at the apex, and tapering to the base. It grows in India.—*C. Æthiopica* is about 18 inches high, with 3—5 pair of oval-lanceolate, downy leaflets; the pods flat and smooth. It grows in the north of Africa.—*C. lanceolata* is an Arabian species, differing from the others in its erect pods.—All these seem to furnish the officinal senna. Linnæus, not aware of the diversity of species, assigned it to one which he named *C. Senna*, but it would be hard to say which has a preferable claim to this name. All the species have the leaflets unequal-sided, by which they are readily distinguished from other leaflets often used for the adulteration of senna, as those of *Argel* (q. v.) and *Bladder Senna*. The commercial names of the different kinds of senna refer to the countries or ports from which they are brought.—*Cassia marylandica* is known as Wild Senna in the middle states of North America.

Bladder Senna (*Colutëa*) is a genus of shrubs of the natural order *Leguminosæ*, suborder *Papilionaceæ*, having pinnated leaves, red or yellow flowers, and remarkably inflated pods, whence the English name. One species (*C. arborescens*) is common in shrubberies in Britain. It is a native of the south of Europe, and is found on the ascent of the crater of Mount Vesuvius—almost the only plant that exists there.

SENNAA'R, a negro state in the south part of Nubia (q. v.), extends from about lat. 15° 30′ to about 12° N., on both sides of the Bahr-el-Azrek, or Blue Nile. Its capital, *Sennaar*, was once an important trading town, but its population has sunk within the last century to about 4000.

SENNA'CHERIB, an Assyrian king, son of Sargon, reigned 702—680 B. C. The interest attaching to his name is principally due to the extraordinary and incomprehensible disaster that befell his army, either at Libnah or at Pelusium, when no fewer than 185,000 Assyrians are said to have been slain by the 'angel of the Lord' (see Hezekiah). The Egyptian account of this mysterious affair (reported by Herodotus, book ii. 141), and that of Berosus the Chaldæan, quoted by Josephus (*Antiq. of Jews*, book x. chap. 1), as well as the scriptural narrative (2 Kings, chap. 18) justify us in believing that S. at least sustained a sudden, unexpected, and terrible overthrow, which forced him to retreat in hurried confusion to his own country. All that we know of his subsequent history is, that he was assassinated by his sons while worshipping his favourite god. The discrepancies, both as regards dates and names in the life of S., between the writer of Kings and profane historians, are felt even by strenuous apologists, like the Rev. George Rawlinson, to be almost, if not altogether irreconcilable. S. belongs to that showy class of eastern monarchs whose rule is commonly described as 'magnificent'—i.e., he built great palaces, and erected monuments in the different parts of his empire, and everywhere left an impression of his grandeur. In Scripture, in Herodotus, in Josephus, S. is the 'Great King.' His most imperial work was the palace at Koyunjik, which covered a space of more than eight acres, and was richly adorned with sculpture.

SENS, an old town of France, in the dep. of Yonne, 70 miles south-east of Paris, stands amid pleasing scenery on the right bank of the Yonne. The town proper is surrounded by walls, chiefly of Roman construction, and in the vicinity, the remains of ancient roads and of Roman camps abound. The spacious and handsome Gothic cathedral is the principal edifice. An active trade in wines, grain, hemp, wool, and timber is carried on. Pop. (1862) 11,098.

SENSA'TION (in Physiology) may be defined to be 'the perception by the mind of a change wrought in the body.' According to this definition, which is borrowed from Dr Todd, sensation involves—first, a bodily change from some cause, whether inherent or external; and secondly, a mental change, whereby the perception of the bodily change is accomplished. The true organ of sensation is the brain, and especially that portion of it which (to use the words of the above-named eminent physiologist) constitutes the centre of sensation, and extends into the spinal cord, forming the posterior horns of its gray matter. See Spinal Marrow. Physiologists distinguish between *common* and *special* sensation. Common sensation exists in the skin, and in all parts of the body to which ordinary sensory nerves are distributed, and is excited by ordinary mechanical or chemical stimuli; while special sensation is exemplified in the special senses of vision, hearing, &c. For the due action of the latter, there are organs of special sensation, which, by the peculiar character of the nerves with which they are supplied, become the recipients of impressions of a particular kind; thus, the eye is sensible to light, the ear to sound, &c.; and if the special nerves going to these organs be irritated, instead of pain being excited, as in the case of an ordinary sensory nerve, there is a feeling closely allied to that which would be excited by the application of the normal stimulus, as light, sound, &c. Any *ordinary* sensibility those organs (the eye, ear, &c.) possess is dependent on ordinary sensory nerves, and is quite independent of the nerves of special sense

In works on the physiology of the nervous system, we often meet with the phrases *objective sensation*, *subjective sensation*, and *reflex sensation*. We shall conclude this article by a brief description of the meaning of these terms. 'In the ordinary mode of exciting sensations,' says Dr Todd, 'the presence of an object is necessary. This object creates an impression on the peripheral parts of the sensitive nerves; and the change caused by this impression being duly propagated to the centre of sensation, is perceived by the mind.' This, which is the ordinary form of sensation, is termed an *objective* sensation, in opposition to a so-called *subjective* sensation, in which a mental act can develop a sensation independently of any present object. These subjective sensations are sometimes excited by the mind recalling, more or less exactly, the presence of an object; but in many cases they are caused by physical changes in the nerves themselves, owing to an excess or deficiency of blood, or some other pathological causes. Thus disordered conditions of the retina or optic nerve may give rise to motes or flashes of light; disturbance of the auditory nerve occasions singing in the ears, the sound of distant bells, &c.

To understand the mode in which *reflex* sensations

are brought about, an acquaintance with *reflex action*, described in the article NERVES AND NERVOUS SYSTEM, is requisite. As examples of this form of sensation may be mentioned the facts, that the irritation of a calculus in the bladder will give rise to pain in the thighs; that diseased liver often excites pain in the shoulder-joint; and that ice or iced drinks suddenly introduced into the stomach, occasion intense pain in the forehead. For further information on the subject, the reader is referred to Dr Todd's article 'Sensation,' in the 4th vol. of his *Cyclopædia of Anatomy and Physiology*.

SENSATION, a name of great import in the Philosophy of Mind, as well as familiar in ordinary speech. In the mental process so named, there is a concurrence of many contrasting phenomena, rendering the word ambiguous, and occasioning verbal disputes.

1. In Sensation, there is a combination or concurrence of physical facts with a mental fact, and the name is apt to be employed in expressing either side. Thus, in sight, the physical processes are known to be—the action of light upon the globe and retina of the eye, a series of nerve-currents in the brain, and a certain outgoing influence to muscles and viscera; these are accompanied by the totally different phenomenon termed the feeling, or the mental consciousness of light. It is to the last fact, the mental fact, that the name Sensation is most correctly applied; but there is a natural liability to make it include those physical adjuncts which are inseparable from the mental manifestation.

2. In the still more comprehensive contrast of Mind and the External or Extended World, both members may be designated under Sensation. One and the same situation on our part may contain a strictly mental or *subjective* experience—pleasure or pain, for example—and an *objective* experience, or a recognition of the extended world, as distinct from mind. In looking at a fine prospect, both facts concur in fluctuating proportions; we have a feeling of pleasure (mind or subject) and a knowledge of the outspread or extended world (object), which is what affects us in the same way at all times, and affects all minds alike. As before, sensation is most properly used to express the strictly mental or subjective experience, the pleasure or the pain, while the 'Perception' should be applied to express the objective experience. See PERCEPTION.

3. In Sensation, a past experience recovered by memory is inextricably woven with the present impression, a circumstance which confuses the boundary-line between Sense and Intellect. The sensation that the full moon gives rise to is not solely owing to the present effect of the moon's rays on the organs of vision; the present effect revives or restores the total ingrained impression of the moon consequent on all the occasions when we have observed it. Again, it is impossible for us to have a sensation without a more or less complex feeling of difference or discrimination, which property is a fundamental fact of intellect. Our sensation of the moon supposes a contrast of the white light with the adjoining blue, of the round form with other forms, of the broad disc with a starry point, and so on. Thus, in Sensation we have a concurrence of all three processes of the intellect—Retentiveness, Agreement, and Difference. Sensation without Intellect is a mere abstraction; it is never realised in fact.

This last remark has important bearings upon the question as to the origin of our knowledge. It has been disputed whether or not our ideas are wholly derived from Sense. Now, seeing that there is no such thing as Sense to the exclusion of Intellect, the question ought to be enlarged and put in this form: Are our ideas wholly derived through Sense in conjunction with the intellectual processes, or are there any ideas that are not or cannot be so derived? When it is alleged, by Cudworth, Price, and others, by way of maintaining the doctrine of Innate Ideas, that Likeness, Unlikeness, Equality, Proportion, &c., are not obtained from sense, the answer is, that their origin may in all probability be accounted for by Sense co-operating with the well-known powers of the Intellect, and that, until the conjunction of the two is proved insufficient, the theory of an Intuitive origin is not called for.

SENSES. Referring for an account of the several senses to their respective designations, we will here endeavour to state what faculties or sensibilities of the mind are properly included under the name.

The common reckoning includes the Five Senses —Taste, Smell, Touch, Hearing, Sight—but this is not now considered exhaustive or complete.

For example, the feelings of Hunger, Thirst, Suffocation, Internal Warmth and Chillness, &c., have all the characters implied in an ordinary sensation: they are the result of some External Agent acting on a distinct bodily organ, and giving rise to Feeling, sometimes pleasurable and sometimes painful. In order that these states, related to the sensibility of the different viscera, may find a place among the Senses, they have been grouped under one general head, and designated 'Sensations of Organic Life.' They are of great importance as regards our enjoyments and our sufferings, although not contributing much to our knowledge or intelligence. They approach nearest to Taste and Smell, the more emotional senses, and are at the furthest remove from the intellectual senses—Touch, Hearing, and Sight.

Again, the feelings connected with our Activity, or with the exercise of the muscular organs—as the pleasures of exercise and rest, the pains of fatigue, the sensibility to weight, resistance, &c.—were, until lately, overlooked in the philosophy of the mind. When they began to be recognised, it was common to treat them as a sixth sense, called the Muscular Sense. But this does not represent their true position. They do not arise from external agents operating on a sensitive part, but from internal impulses proceeding outwards to stimulate the muscular energies, and to bring about movements; they are thus the contrast of the senses generally. Sense is associated with the *ingoing* nerve-currents, Movement with the *outgoing*. The contrast is vital and fundamental; and accordingly, the Feelings of Movement and Muscular Strain should be considered as a genus distinct from the genus Sense, and not as a species of that genus.

The classification of the fundamental sensibilities of the mind would then stand thus: I. Feelings of Muscular Energy. II. Sensations of the Senses, 1. Organic Life; 2. Taste; 3. Smell—Emotional: 4. Touch; 5. Hearing; 6. Sight—Intellectual.

SENSIBI'LITY is a term somewhat vaguely used by physiologists. Until a comparatively recent period, it was often confounded with Irritability, although Haller, more than a century ago, very clearly laid down the distinction between these two properties of tissues. We not unfrequently find it applied to nerves, to signify their power of evolving nervous force, but Excitability (as Dr Todd observes) more exactly implies what is meant in this case. The term should be limited to signify the power which any part of the body possesses of causing changes, inherent or excited in it, to be perceived by the mind; and the greater this power is, the greater is the sensibility of the part. The degree of sensibility of different parts of the outer

surface of body is very various. The relative sensibility has been ascertained by Weber by touching the surface with the points of a pair of compasses tipped with cork, and then (the subject's eyes being closed) by approximating the points until they were brought within the smallest distance at which they could be felt to be separate. The following are a few of his results: point of tongue, ½ a line; tips of fingers, 1 line; red surface of lips, 2 lines; palmar surface of 2d phalanx, 2 lines; palmar surface of metacarpus, 3 lines; tip of the nose, 3 lines; palm of the hand, 5 lines; dorsum of the hand, 8 lines; vertex, 15 lines; skin over the spine and the middle of the thigh, each 30 lines: so that the sensibility of the skin is at least sixty times greater in some parts than in others.

SE'NSITIVE PLANT, a name commonly given to certain species of *Mimosa* (see MIMOSEÆ), on account of the peculiar phenomena of Irritability (q. v.) which their leaves exhibit in their collapse when touched or shaken. Numerous species of *Mimosa* possess this property, and, indeed, most of the species in a greater or less degree; but those in which it is most conspicuous are humble herbaceous or half-shrubby plants. They have leaves beautifully divided, again and again pinnate, with a great number of small leaflets, of which the pairs close upwards when touched. On repeated or rougher touching, the leaflets of the neighbouring *pinnæ* also close together, and all the pinnæ sink down, and at last the leaf-stalk itself sinks down, and the whole leaf hangs as if withered. If the stem is shaken, all the leaves exhibit the same phenomena. After a short time, the leaf-stalk rises, and the leaflets expand again. On account of this curious and interesting property, some of the sensitive plants are frequently cultivated in our hot-houses. They are generally treated as annuals, although capable of longer life. *M. sensitiva*, one of the best known species, is a native of Brazil, with prickly stems and leaf-stalks, and small heads of rose-coloured flowers, *M. pudica* has a herbaceous stem, bristly, but not prickly. *M. casta*, *M. pudibunda*, *M. palpitans*, and *M. viva*, are also among the most sensitive species.

SENSO'RIUM. This term is applied by physiologists to a series of ganglionic centres, each of which has the power of communicating to the mind the impressions derived from the organ with which it is connected, and of exciting automatic or involuntary muscular movements in respondence to these sensations. (See Carpenter, *On the Functions of the Nervous System in Human Physiology*, 6th ed. p. 545.) These ganglionic centres, which lie at the base of the brain in man, are in direct connection with the nerves of sensation, and appear to differ entirely in their functions from the other parts of the encephalon. Anterior, there are the *olfactive* ganglia, or what are termed the bulbs of the olfactive nerves. The ganglionic nature of these structures is more evident in many of the lower mammals, in whom the organ of smell is highly developed, than it is in man, although even in the human subject these masses contain gray or vesicular nervous matter, indicating their true ganglionic nature. Behind these, we have the *optic* ganglia, commonly known as the corpora quadrigemina, small in man, but comparatively large in many of the lower mammals. The *auditory* ganglia do not form distinct projecting masses, but are represented by small masses of vesicular matter, into which the auditory nerves may be traced, and which are imbedded in the medulla oblongata. In fishes, there is a well-developed and distinct auditory ganglion. The *gustatory* ganglion is the least distinct of any, but it is supposed to be represented by a mass of vesicular matter embedded, like the preceding ganglion, in the medulla oblongata, and into which the nerves of taste may be traced. On examining a progressive series of brains from man to the lowest mammals, we find a continuous diminution of the hemispheres, and a corresponding development of these ganglia, or, at all events, of the olfactory and optic ganglia; while, if we continue the investigation to the brains of birds, reptiles, and fishes, we find the same law in force, till finally, in reptiles and fishes, those ganglia form the greatest part of the brain.

It was long attempted to determine some one point in the brain where the soul is more especially located or centralised; and to this ideal point the name of Sensorium was applied in the older psychological speculations. The fancy of Descartes made it a small body near the base of the brain, called the 'pineal gland.' The recent views of the nervous system repudiate the idea of a central point of this nature; in consciousness, the brain generally is active, although, under different impressions and ideas, the currents may be presumed to follow different nerve-tracks. Consequently, no meaning is now attached to a sensorium in psychology, as distinct from the cerebrum at large.

SENTENCE. A sentence is the form of words in which a thought or a Proposition (q. v.) is expressed. A mere phrase or group of words, such as, 'A very high mountain,' which only conveys a meaning or calls up an idea, but does not make an affirmation, is not a sentence. Since speech is the expression of thought, the sentence is the proper unit or integer of speech, and thus forms the starting-point in the study of language.

Every single sentence is made up of two parts—the one naming the subject, or the something that is spoken about; the other the predicate, or the something that is said of it—as, 'The sun—shines;' 'Those who have the greatest gifts, and are of the greatest usefulness—are the most humble.' Every sentence must contain a finite verb, as it is the function of the Verb (q. v.) to make affirmations. 'The sun shines,' is an example of a sentence in its barest form, containing merely the subject 'sun,' and the predicate 'shines,' which are called the *principal* elements. The enlargement or development of the sentence takes place by means of adjuncts, or *secondary* elements, tacked on to the principal elements—as, '*Young* birds build *nests without experience*.' Sentences may be divided into simple, compound, and complex.

1. A simple sentence has only one subject and one finite verb. Reduced to its essentials, it is of the form, 'The sun shines;' 'The day is cold.' 2. A compound sentence consists of two or more simple sentences combined—as, 'The sun gives light by day, and the moon by night;' which contains two affirmations or sentences, 'The sun gives light by day,' and 'The moon gives light by night.' 3. A complex sentence consists of one principal sentence together with one or more dependent sentences. In the compound sentence given above, there are two distinct statements, and as both are put on the same footing, they are said to be *co-ordinate* sentences. But when we say, 'The moon rose as the sun went down,' the going down of the sun is not mentioned on its own account; the only thing directly affirmed is that the moon rose at a certain time, and the going down of the sun is only introduced as marking that time. Such clauses are called *subordinate* sentences (see CONJUNCTIONS). The subordinate clauses of complex sentences may be considered as transformations of the elements of the simple sentence; and according to the nature of the element which has been transformed, they

might be called noun-sentences, adjective-sentences, or adverbial sentences—e. g., '*The existence of God* is denied by none' = '*That God exists*, is denied by none.' '*Benevolent* men are happy' = 'Men *who seek the good of others* are happy.' 'The moon rose *at sunset*' = 'The moon rose *as the sun went down*.' Further, the nouns, adjectives, and adverbs that enter into a subordinate sentence, may, one and all of them, be transformed in their turn into sentences, which will thus be subordinate in a still higher degree—e. g., 'Europe rejoiced *that Greece was delivered from that oppressive power*' = 'Europe rejoiced *that Greece was delivered from the power that had oppressed her*.' Here the adjective *oppressive* in the first sentence has in the second been converted into a sentence which is directly dependent, not on the principal sentence (Europe rejoiced), but on the subordinate, and is therefore subordinate in the second degree. Subordination is seldom carried beyond the second or third degree, as it becomes perplexing, and weakens the force of the principal assertion. The same sentence is often compound, as containing two or more co-ordinate sentences, and at the same time complex, as containing one or more subordinate sentences in addition; and to discriminate all these and point out their relations, is to give the syntactical analysis of the sentence.

SE'NTINEL, SENTRY (from the Lat. *sentire*, to feel or perceive, through the Ital. *sentinella*), a private soldier, marine, or sailor, posted at a point of trust, with the duty of watching the approach of an enemy, or any person suspected of hostile intentions. Sentries mount guard over dépôts of arms, the tents of commanding officers, &c. During the night, each sentry is intrusted with the 'word,' or countersign; and no person, however exalted in position, may attempt to approach or pass him without giving that as a signal. In such case, the sentry is bound to arrest the intruder, and, if necessary, to shoot him. It has happened before now that the commander-in-chief of an army has been prisoner in the hands of one of his own sentries. When an army is in the field, the sentries are its eyes, for they guard the approaches in every direction some distance in front of the main body of troops. In the event of attack, they give the alarm, and retire slowly on their supports. There is usually an agreement, tacit or expressed, between commanders that their outlying sentries shall not fire upon one another, which would only be productive of useless bloodshed. Under martial law, death is the penalty to a sentry for sleeping on guard.

SE'NZA SORDI'NO (Ital. without the mute, or without the damper), a musical term, which, when applied to the violin or violoncello, denotes that the Mute (q. v.) is to be removed. In pianoforte music, it means that the performer must press down the pedal which takes off the dampers.

SEPAL. See CALYX.

SEPARATE ESTATE is the legal term denoting the property of a married woman, which she holds independently of her husband's interference and control. Where a marriage is about to be entered into, and the lady has property, it is usual, before the marriage, for her to assign and convey to trustees all or part of her property, so that it may continue to be vested in them for her exclusive benefit, and so that she may be able to deal with it in much the same manner as if she were not married. The deed in that case entirely regulates the extent of her rights. Where the deed has been properly executed, she can draw the interest, and do what she pleases with it. A third party who bequeaths property to a married woman, may also so give it as to make it separate estate. If there is no clause in the deed or will prohibiting alienation or anticipation, she will be able to dispose of her life-interest. She can, in general, alienate her separate estate without the husband's consent; and she is not bound out of it to maintain the husband, even though he may be destitute; nor is she bound to maintain her children, unless the latter would otherwise be chargeable to the parish. When a wife incurs debts and liabilities, her separate estate will become chargeable with these, unless she was at the time acting only as the agent of the husband, such as ordering necessaries for the house. For the general principles of American law as respects the rights of married women, and decisions relative to the married women's acts of Pennsylvania, see FEME COVERTE.

SEPARATION of married persons is either judicial or voluntary. If the parties enter into a deed, or other arrangement, to live separate, this is called a voluntary separation, and, in general, the legal rights of the parties are not altered, except that if the wife is provided with maintenance, she has no longer an implied authority to bind the husband. And though voluntary separation is not encouraged by courts of law, yet effect will be given frequently to deliberate contracts of this kind entered into between the parties. See JUDICIAL SEPARATION.

SE'PARATISTS. See QUAKERS, OATH.

SE'PIA AND SEPI'ADÆ. See CUTTLE-FISH.

SEPIA, a pigment used as a water-colour. It is prepared from the secretion of a peculiar organ, called the ink-bag, found in the Dibranchiate *Cephalopoda*, or Cuttle-fishes. This secretion is black at first, and insoluble in water, but extremely diffusible through it; it is therefore agitated in water to wash it, and then allowed slowly to subside, after which the water is poured off, and the sediment, when dry enough, is formed into cakes or sticks. In this state it is called 'India Ink.' If, however, it is dissolved in a solution of caustic potash, it becomes brown, and is then boiled and filtered, after which the alkali is neutralised with an acid, and the brown pigment is precipitated and dried: this constitutes the proper sepia. It is usually prepared in Italy, great numbers of the species which yields it most abundantly, *Sepia officinalis*, being found in the Mediterranean. The black kind, called India Ink, is prepared in China, Japan, and India, and forms the common writing-ink of those countries.

SE'POY, corrupted from the Indian word *sipahi*, a soldier. This word sipahi, in its more familiar form of *spahis*, is known in most eastern armies; and is itself derived from *sip*, a bow and arrow, the ordinary armament of an Indian soldier in ancient times. The word sepoy now denotes a native Hindu soldier in the British army in India. See EAST INDIA ARMY. The present sepoy force does not exceed 120,000.

SEPS. See SKINK.

SEPTA'RIA are ovate flattened nodules of argillaceous limestone, internally divided into numerous angular fragments by reticulating fissures radiating from the centre to the circumference, which are filled with some mineral substance, as carbonate of lime or sulphate of barytes, that has been infiltrated subsequent to their formation. The fissures have been produced by the cracking of the nodule when drying. They are largest and most numerous in the centre, and gradually decrease outwards, shewing that the external crust had first become indurated, and so, preventing any alteration in the size of the whole mass, produced wider rents

as the interior contracted. The radiating figure, and the striking contrast between the dark body of argillaceous limestone and the more or less transparent sparry veins, when the nodule is cut and polished, has caused them to be manufactured into small tables and similar objects. They are, however, most extensively employed in the manufacture of cement. As they are composed of clay, lime, and iron, they form a cement which hardens under water, and which is known commercially as Roman cement, because of its properties being the same as a famous hydraulic cement made of ferruginous volcanic ash brought from Rome. Septaria occur in layers in clay deposits, and are quarried for economical purposes in the clays of the London basin. Large numbers are also dredged up off Harwich, which have been washed out of the shore-cliffs by the waves. The nodules generally contain a scale, shell, plant, fruit, coprolite, or some other organic substance, forming the nucleus that has apparently excited the metamorphic action which withdrew from the surrounding clay the calcareous and ferruginous materials scattered through it, and aggregated them around itself.

SEPTE'MBER (Lat. *septem*, seven) was the 7th month of the Roman calendar, but is the 9th according to our reckoning, though we preserve the original name. Various Roman emperors, following the example of Augustus, who changed 'Sextilis,' the sixth month of the Roman calendar, into 'Augustus' (August), attempted to substitute other names for this month, but the ancient appellation continued to hold its ground. The Saxons called it *gerst-monath*, or barley-month, because barley, their chief cereal crop, was generally harvested during this month. It has always contained 30 days.

SEPTE'MBRISTS, SEPTEMBRI'SERS (Fr. *Septembriseurs*), the name given to the frantic executioners in what are known as the 'September massacres' in Paris. The particular causes of this ferocious outburst were twofold—mad fear of domestic traitors and of foreign despots. The news came pouring into Paris, ever more and more maddening, of Prussian and Austrian hordes marching victorious over the frontiers; insolent royalists obtruding themselves in the van of the invading armies, and breathing threatenings and slaughter; while numerous *aristocrates* (i. e., favourers of the king and court) were believed to be making preparations to receive them in Paris. At the very same moment broke out the royalist insurrection in *La Vendée*, rendering France still further delirious, whereupon Danton, 'minister of justice,' got a decree passed, August 28, 1792, ordering domiciliary visits for the arrest of all suspected persons, and for the seizure of arms of which patriotic France stood much in need. Upwards of 2000 stand of arms were got in this way, and 400 head of new prisoners. On the morning of September 2, the news of the capture of Verdun by the Prussians arrived. The mingled rage and panic of the people cannot be described. All the bells in Paris were set a-clanging; men and women hurried in myriads to the *Champ de Mars* to get themselves enrolled as volunteers. Danton entered the legislature — 'the black brows clouded, the colossus-figure tramping heavy, grim energy looking from all features of the rugged man'—and made that famous speech, ending: 'Pour les vaincre, pour les atterrer, que faut-il? De l'audace, encore de l'audace, et toujours de l'audace.' The effect was electrical. He obtained from the Assembly a decree condemning to death all 'who refused to march to the frontiers or to take up arms.' But patriotism against foreigners was not enough. Were not the traitors at home deserving of death? Marat thought so: multitudes of ardent frantic men and women shared his conviction; but it is not proved that either Marat or Danton formally ordered the massacres, or, indeed, that anybody ordered them. They were rather the spontaneous outburst of patriotic insanity, beholding aristocratic treachery and plots everywhere. Priests, Swiss soldiers, aged and infirm paupers, women both reputable and disreputable, and criminals, were mercilessly cut down or shot. From Sunday afternoon till Thursday evening the wild butchery went on at the Bicêtre, the Abbaye, the Convent of the Carmelites, the Conciergerie du Palais, the Grand Châtelet, St Firmin, La Force, and the Salpétrière. One gathers a glimpse of the savage sincerity of the Septembriseurs when one reads that the gold rings, watches, money, &c. found on the persons of the massacred were all religiously brought to the town-hall; not a single thing was stolen or furtively appropriated until after the essential work was done. Then the roughs or blackguards ('sons of darkness,' as Carlyle calls them) sallied out into the streets like Mohawks or Alsatians, and commenced to plunder, but were speedily suppressed and forced back into their dens.

Great misapprehension prevails as to the numbers who perished in these fearful scenes. Royalist pamphleteers and others, trusting mainly to fantasy (according to Carlyle, *Fr. Rev.*, vol. ii. p. 158), reckon the victims at 3000, 6000, and even 12,000; but the accurate advocate Maton (who was in the thick of the horrors, and narrowly escaped the guillotine) reduces the number, by 'arithmetical ciphers and lists,' to 1089, which, be it observed, included numbers of forgers of assignats, and other criminals. It was a sad and horrible affair, as all massacres are; but it is above all things desirable to know exactly the *dimensions* of, and the motives that stirred the actors in, so execrable a tragedy.

SEPTIMOLE, in Music. When a note is divided into seven instead of four parts—for example, a minim into seven quavers, or a crotchet into seven semiquavers—the group is called a septimole, and the figure 7 is generally placed over it.

A septimole may also occur in a $\frac{6}{8}$ measure, in which case the seven notes are collectively of the value, not of four, but of six.

SEPTUAGE'SIMA SUNDAY (Lat. *Septuagesima*, 'the seventieth'), the third Sunday before *Lent* (q. v.), so called, like 'Sexagesima' and 'Quinquagesima,' from its distance (reckoned in round numbers) before Easter.

SE'PTUAGINT (Gr. *Hoi tōn O*, or *hoi O*; Lat. *Septuaginta*; Seventy, LXX., Alexandrine version, &c.), the most ancient Greek translation of the Old Testament that has come down to us, and the one commonly in use among the Jews at the time of Christ. Its origin is shrouded in deep obscurity. The principal myth about it—repeated by Philo, Josephus, the Talmud, and the Church Fathers (Justin, Clement of Alexandria, Epiphanius, and the rest), with individual variations—is contained in a letter purporting to be written by a Greek, Aristeas, to his brother, Philokrates, during the reign of Ptolemy Philadelphus (284—247 B. C.). This king, it is stated, anxious to embody in a collection of laws of all nations on which he was engaged, also those of the Jews, invited, by the advice of his librarian, Demetrius Phalereus, 72 men of learning and eminence from Palestine, who performed the task of translation

(on the isle of Pharos) in 72 days. The facts upon which this legend—utterly rejected now as a piece of history—rests, cannot well be ascertained now. So much, however, seems clear from another anterior testimony (Aristobulos), that Ptolemy, aided by Demetrius, did cause a Greek version of the Pentateuch to be executed, probably during the time of his being co-regent of Ptolemy Lagi. That the translator or translators, however, were not Palestinian but Egyptian Jews, appears equally clear both from the state of the text from which the translation must have been made, and from the intimate acquaintance with Egyptian manners and customs which it evinces. This text differs, especially in the Pentateuch, considerably from our received text, but agrees in many instances with the Samaritan (q. v.). The question of the number of translators has been much and warmly discussed, but with little positive result. So much only seems certain, that different hands were employed in the rendering of the different parts of the Pentateuch, upon which infinite care was bestowed, as well as of the other books of the Old Testament, which, indeed, do not seem to have been done at the same time. In some instances, it would appear as if the translation had been made before the non-pentateuchial books were united with the others into one canon. This seems particularly evident in the case of the book of Jeremiah, which, in the translation, appears in a more primitive form than in the state in which we possess it now. In a less degree does this discrepancy appear in Job, the Proverbs, Daniel, and Esther; of these, however, our canon probably contains the original form, while the LXX. shews later variants. It is, however, in neither of these books to be decided now whether the discrepancies observable are due to an already altered text upon which the translators worked, or whether they were their own emendations; or even whether many of them are not due to a much later period. The translation of the book of Daniel is the most flagrant instance of subsequently introduced 'corrections' and additions. Apart from the apocryphal pieces attached to it, its obscure passages were 'emendated' to such an extent by both Jews and Christians, that it was by the authority of the early Church utterly rejected, and replaced by the version of Theodotion. The translator of Job, though less arbitrary, has yet altered, added to, and abbreviated considerably, his text. Esther has many apocryphal additions, which owe their origin probably to the Alexandrine period, and never existed in Hebrew. Of exaggerated literalness is the version of Ecclesiastes and the Psalms. Among the most successful books are to be mentioned the Psalms and Ezekiel. But, on the whole, there is to be noticed throughout, a lack of an exact knowledge of the original, a striving after minute fidelity in one part, and an unbridled arbitrariness in another; further, a desire to tone down or to utterly eliminate anthropomorphisms or anything that appeared objectionable to the refined taste of the time.

The Septuagint was held in the very highest repute among the Alexandrine Jews, while the Palestinians looked upon it as a dangerous innovation, and even instituted the day of its completion as a day of mourning. Gradually, however, it also found its way into Palestine, and at the time of the composition of the New Testament, it seems almost to have superseded the original, considering that its quotations from the Old Testament are almost invariably given from the LXX. It was read and interpreted in the synagogues for some centuries after Christ, until the increasing knowledge of the original, fostered by the many academies and schools, and the frequent disputations with the early Christians, brought other and more faithful and literal translations, such as that of Aquila, Theodotion, &c., into use, and gradually the LXX. was altogether discarded in the synagogue. The Church, however, for a long time, and the Greek Church up to this day, considered it as of equal authority and inspiration with the Hebrew text itself; and many translations were made from it into the vernaculars of different Christian communities (the Itala, the Syriac, the Ethiopian, Egyptian, Armenian, Georgian, Slavonian, &c.). The large diffusion of the LXX. among the Hellenists and the churches, and the want of anything like a critically fixed text, together with the pious desire bodily to insert the peculiar explanation given to obscure passages by single authorities, the ignorance of the copyists, and a number of other causes, contributed not a little to render the MSS. corrupt, in some instances past mending. Nor were the endeavours of Origen (q. v.) in his *Hexapla*, or of Lucianus and Hesychius for a restoration of the proper text, of any avail. The principal MSS. that have, as far as we know, survived are the Codex Alexandrinus in the British Museum, the Codex Vaticanus in Rome, and the Sinaitic Codex (imperfect) in St Petersburg; all of which belong to the time between the 4th and 6th centuries A. D. The principal editions are the Complutensian (1514—1517), reprinted in the Antwerp and Paris Polyglot; the Aldine of Venice (1518); the Sixtine of Rome (1587), partly reprinted in Walton's Polyglot (1657) by Lamb Bos. (Franeker, 1709); Reineccius (Leip. 1730); Parsons and Holmes (Oxford, 1798—1827); Tischendorf (1850, &c.). Following more closely the Codex Alexandrinus is the edition of Grabe (Oxford, 1707—1720, completed by F. Lee), reprinted by Breitinger (Zürich, 1730—1732) and others. The Alexandrine Codex has been reproduced in facsimile by H. H. Baber; the Sinaitic in the same manner by Tischendorf. Some other MS. recensions are mentioned by the early Fathers, such as the 'Hebrew,' the 'Syrian,' the 'Samaritan,' the 'Hellenian,' &c. The literature of the LXX. is very large, and special grammars and dictionaries have been compiled for its peculiarly corrupt idiom.

SEPU'LCHRAL MOUND. The practice of rearing mounds of earth and stone over the resting-place of the dead may be traced to remote antiquity. It had doubtless its origin in the heap of earth displaced by interment, which, in the case of the illustrious warrior or chief, it became the practice to raise into the size and form of the barrow or tumulus which is found all over Northern Europe, from Great Britain and Ireland to Upsala in Sweden, and the Steppes of Ukraine. Sepulchral mounds of some sort seem, indeed, to have been erected among all the nations of Asia as well as of Europe, and they are found in numbers in Central America. Some of the larger tumuli or moathills are but partially artificial; natural mounds having been added to or shaped into the form which it was wished that they should take. There is considerable diversity in the form of the tumuli, the different forms corresponding to different periods, considerably remote from each other. The oldest are long-shaped, and in the form of gigantic graves, often depressed in the centre, and elevated towards one end. Inside the tumulus, the body was laid at full length, often along with spear and arrow heads of flint and bone. The bell and bowl-shaped tumuli seem to have succeeded this early form. Within them is often found a short cist and primitive cinerary urn, shewing that the body had been burned; but there appears also to be evidence that the processes of inhumation and cremation had been in use contemporaneously, or sometimes the body was placed within the cist in a sitting posture. Skeletons of dogs and

horses are occasionally found beside the ashes of the deceased. The sepulchral mounds which seem to be of latest date are broad and low, surrounded sometimes by an earthen vallum, and sometimes, particularly in Scotland and Scandinavia, by a circle of standing stones. In both the enclosed and encircled tumuli, weapons have been found belonging to the period when the metallurgic arts were practised, and in some instances Roman as well as native relics. A remarkable form of tumulus frequent in Sweden, and occasionally seen in Scotland, consists of an oblong mound larger than the primitive barrow, and terminated at both ends in a point, whence it has been called the *skibs ælunger*, or ship-barrow. Scandinavian antiquaries have come to the conclusion that the bodies of the warriors of the deep were sometimes burned in their ships, whose form was repeated in the earthwork reared above their ashes.

The most numerous class of sepulchral mounds in Scotland are the *cairns* (q. v.) or tumuli of stone, which abound in every district of the country, and were often of much larger dimensions than the earthen tumuli. Another species of monument is the *cromlech* (q. v.).

SEPULVEDA, JUAN GINES DE, a Spanish historian, surnamed the Livy of Spain, was born at Pozo-blanco, in the neighbourhood of Cordova, about 1490, studied first at Cordova and Alcala, and went to Bologna in 1515, where he obtained the acquaintance and esteem of the most celebrated savans of Italy and Spain. There he wrote the life of Cardinal Albornoz, which was published in 1521. He assisted Cardinal Cajetan at Naples in revising the Greek text of the New Testament, and in 1536 returned to Spain as chaplain and historiographer to Charles V., and preceptor to his son, afterwards Philip II. Died in 1573 or 1574. Erasmus speaks of S. in the *Ciceronianus* in terms of high encomium, and there is indeed little doubt that he was one of the most learned men and best writers of his time. His works comprise Latin translations of part of Aristotle (1531), and of the commentary of Alexander Aphrodisiensis (1527); miscellaneous dissertations, among which were treatises on Fate and Free-will, in opposition to Luther (1526), in favour of a war with the Turks (1529), in defence of Alberto Pio Cardinal Carpi (1531), on Marriage (1531), and in support of the congruency of the military profession with Christianity (1541), on Monarchy and the Duty of Kings (1571). His histories of the Reign of Charles V., of that of Philip II., and of the Conquests of the Spaniards in Mexico, all of them written in Latin, are still inedited. His other works were collected and published by the Royal Academy of History at Madrid in 1780 (4 vols. fol.), accompanied with a portrait of S., and an account of his life and writings.

SEQUESTRA'TION, the Scotch legal term for Bankruptcy (q. v.).—In English law, sequestration is the appropriate term denoting the process by which the creditor of a clergyman of the Church of England in possession of a living, sues out execution on his judgment, and obtains payment of the debt. In ordinary cases of lay debtors, the sheriff takes possession of the real estate of judgment debtors; but when the debtor is a clergyman, the bishop puts in force the law, and appoints sequestrators to take possession of the benefice, and draw the emoluments, and pay them over to the creditor, first making due provision for the proper celebration of divine worship.

SE'QUIN (Ital. *zecchino*, from *zecca*, the name of the Venetian mint), a gold coin first struck at Venice about the end of the 13th c., was about the size of a Ducat (q. v.), and was equivalent to about 9*s.* 4*d.* sterling. Coins of the same name, but varying in value, were issued by other states.

SERA'GLIO (properly, SERAÏ) is the palace of the sultan at Constantinople. It stands in a beautiful situation on a head of land projecting into the sea, known as the Golden Horn, and is enclosed by walls 7½ miles in circuit. Within the walls are a variety of mosques, gardens, and large edifices, capable of containing 20,000 persons, though the whole number of the inhabitants scarcely ever reaches the half of this. The principal entrance (*Babi Humayun*, or Sublime Gate) is a kind of pavilion, which is constantly guarded by *capidjis*, or officers of the seraglio; and the chief of the large edifices within is the *harem* (Arab. sacred spot), which is distinctly separated from the rest of the seraglio, and consists of a group of houses and gardens, one of each being possessed by each of the sultan's wives, and of the habitations of the concubines and slaves. The harem is ruled by the *kiaja-khatun*, or inspector of the women, who is under the sultan's authority alone, and is supplied with what they require by the *kislar-aga*, or chief of the black eunuchs who form the principal or inner guard of the harem. The second and outer guard is given to the white eunuchs, under their chief the *kapu-agassy*, or *kapu-oghlan*. Other classes of household officers are the *mutes* (Turkish, *bisebân* or *dilssis*), who, till recently, were the executers of the sultan's orders, especially those in which the utmost secrecy was required; the *bostanjis*, or gardeners; the *baltajis*, or cleavers of wood; and the *itsh-oghlans*, or attendants of the sultan. The sultan's mother always resides within the seraglio, but his sisters do not. Access may easily be had to the seraglio, with the exception of the harem, which is scrupulously guarded from even the eyes of strangers. The English have very improperly confounded the two terms 'seraglio' and 'harem.'

SERA'JO. See BOSNA-SERAI.

SERAMPO'RE, a neat town of British India, built in the European style, and extending a mile along the right bank of the Hooghly, 14 miles north of Calcutta. Paper is here manufactured in large quantity. S. was at one time a Danish settlement, but was transferred by purchase to the British in 1845. Pop. about 15,000.

SERANG. See CERAM.

SERA'PEUM (Gr. *Serapeion* or *Sarapeion*), a temple so named in honour of Serapis (q. v.), several of which are known to have existed in the ancient world. The most remarkable of these temples was that of Alexandria, which was situated south of the canal, and outside the walls of the city, and superseded an older temple at Rhacotis. Hither was transported the statue of Dis or Pluto from Sinope by Ptolemy I., and attached to it was the celebrated Alexandrian Library (q. v.). The S. at Memphis attained scarcely less reputation, and consisted of a group of temples dedicated to Astarte, Anubis, Imouthos or Æsculapius, and Serapis. It was approached from the city of Memphis by an avenue of sphinxes, which had already become partially buried in the sands in the days of Strabo, and were discovered by M. Mariette in 1850, who, after a series of excavations, uncovered the ruins, and discovered the cemeteries of the mummied Apis or Bulls sacred to Ptah and Osiris at Memphis. Close to the S. was the Apeum, or temple of the living Apis, in which the bull lived, as well as the cow which had produced him. The S., or, as it was called in Egyptian, the abode of *Osor-hapi*, or the Osiris-

Apis, was, in fact, the sepulchre of the bull. The most remarkable part of the work, which was of great extent, was the subterranean tombs of the mummies of the Apis, consisting of galleries with numerous chambers, in which the remains of these bulls had been deposited from the reign of Amenophis III. of the 18th dynasty, about 1400 B. C., till the time of the Romans. Two principal galleries contained the tombs. The second gallery, commenced in the 53d year of Psammetichus I., was on a grander scale than the first, with larger sepulchral chambers, and magnificent sarcophagi of granite, measuring sometimes 12 feet high, 15 feet long, and weighing many tons. During the reign of the Persians, and subsequently, the chambers decreased in size, and the monuments exhibit the general decadence of the arts. The Apis, considered as the incarnation of the god Ptah during life, received royal and divine honours after death; his body, or the principal portion, being embalmed, and a sepulchral tablet or tombstone placed on his sepulchre, along with other tablets of different worshippers, who adored his divinity, and dedicated them to the deceased bull. As the principal tombstone of the bull contained the dates of the king's reign in which he was born or discovered, enthroned in the Apeum, and died or was buried in the S., these tablets have become an important element for the chronology of the 19th and subsequent dynasties, and have aided to fix some of the hitherto doubtful points of the chronology of the period. They terminate with Ptolemy Euergetes II., 177 B. C. The tablets, votive and sepulchral, amounted to about 1200, and the most remarkable are at present in the Museum of the Louvre at Paris. Numerous bronze figures and other antiquities were found during the excavations, comprising costly objects of jewellery, many of which are also in the Louvre. Besides these, several Greek papyri which appear to have formerly belonged to the library or archives of the S. were previously known, and many have been published. These throw great light upon the constitution of the hierarchy of the S., amongst which was a kind of order of monks, who lived within the precincts of the building, beyond which they did not go, and subsisted upon alms or the contributions of their family.—Mariette, *Serapeum de Memphis* (4to, Paris, 1856); *La Mère d'Apis* (4to, Paris, 1856); *Athen. Fran.* (4to, Paris, 1855—1856); Lepsius, *Ueber den Apis-kreis, Zeitsch. d. Morg. Gesell.* (8vo, Leip. 1853).

SE'RAPHIM (plural of *Seraph*), celestial beings in attendance upon Jehovah, mentioned by Isaiah. They are similar to the Cherubim (q. v.), have the human form—face, voice, two hands, and two feet—but six wings, with four of which they cover their face and feet—as a sign of reverence—while with two they fly. Nothing is more uncertain than the origin of this conception, or of the word which expresses it. Their office of singing the praises of Jehovah's greatness, and of being the swift messengers between heaven and earth, does not go far to explain it. Deserving of consideration, however, considering the close contact between Judæa and Assyria and Babylon, both before and after the Captivity, is a comparison between the S. and the winged men and beasts that have been brought to light in these last-named countries.

SE'RAPHINE, a keyed musical instrument in which the sounds were produced by the action of wind on free vibratory reeds. It was the precursor of the Harmonium (q. v.).

SERA'PIS, or SARAPIS, the Greek name of an Egyptian deity, introduced into Egypt in the time of Ptolemy I., or Soter. This monarch is said to have seen the image of a god in a dream, commanding him to remove it from the place were it was; and Sosibius, a traveller, having recognised it as existing at Sinope, Soteles and Dionysius where sent from Egypt, and brought it from Sinope to Alexandria. On its arrival, it was examined by Timotheus the interpreter and the celebrated Manetho, who called it Serapis, and appear to have identified it with Osorhapis, or Osiris united with Apis, i. e., Osiris, in his character of the Egyptian Pluto, as a deity of similar character. The figure, in fact, appears to have been one of Hades or Pluto, having at its side Cerberus, and a dragon or snake. According to some authorities, the statue of S. was sent to Ptolemy II., or Philadelphus, because that monarch had relieved the city of Sinope from famine by supplying it with corn, and the statue was placed in the Serapeum, at the promontory of Rhacotis. The S. of the Ptolemaic period, however, was not an Egyptian, but a Greek deity, whose temple was not admitted into the precincts of Egyptian cities, and only found favour in the Greek cities founded in Egypt. It is said that 42 temples were erected under the Ptolèmies and Romans to this god in Egypt. His resemblance to Osiris consisted in his chthonic or infernal character, as judge of the dead and ruler of Hades. About his nature and attributes the Greeks themselves entertained very different ideas, some considering him allied to the Sun, others to Æsculapius or Hades. The god had a magnificent temple at Alexandria, to which was attached the celebrated Library; another at Memphis, in the vicinity of the cemetery of the mummies of the Apis, which has been recently excavated by M. Mariette; and another temple at Canopus. From recent discoveries, it appears that he represented or was identified with the Hesiri Api, or Osorapis, the 'Osirified' or 'dead Apis,' who was also invested with many of the attributes of Osiris, and considered, while living, to be the incarnation of the god Ptah-Socharis-Osiris, the tutelary divinity of Memphis. The worship of S., introduced into Egypt by the Ptolemies, subsequently became greatly extended in Asia Minor; and his image, in alliance with that of Isis and other deities, appears on many of the coins of the imperial days of Rome. In 146 A.D., the worship of the god was introduced into the city of Rome by Antoninus Pius, and the mysteries celebrated on the 6th May; but they were not long after abolished by the senate, on account of their licentious character. A celebrated temple of S. also existed at Puteoli (Pozzuoli), near Naples, and the remains of it are still seen, and present curious geological phenomena. In Egypt itself, the worship of the deity subsisted till the fall of paganism, the image at Alexandria continuing to be worshipped till destroyed, 398 A.D., by Theophilus, archbishop of that town. Busts of S. are found in most museums, and his head or figure engraved on certain stones was supposed to possess particular mystic virtues. His temples were oracular, the votaries consulting him by sleeping and dreaming in them; and at Alexandria the priests connected his worship with the healing art.—Plutarch, *De Isid*, s. 28; Clemens, *Orat. Adhort.* p. 21; Tacit. *Hist.* iv. c. 83, 84; Strabo, Lib. xvii. p. 552; Macrobius, *Saturn*, i. 7, 25; Nixon, *Dell' Edifizio di Pozzuoli detto il Tempio di Serapide* (Nap. 1773); Wilkinson, *Mann. and Cust.* iv. p. 360; Gibbon, *Decline and Fall*, c. 28.

Serapis.
From a Seal in the British Museum.

SERA'SKIER, or SERI-ASKER (Pers. head of the army), the name given by the Turks to every general having the command of a separate army, and, in particular, to the commander-in-chief or minister of war. The seraskier, in the latter sense, possesses most extensive authority, being subordinate only to the sultan and grand vizier; he is selected by the monarch from among the pashas of two or three tails.

SERENA'DE (Ital. *serenata*), originally music performed in a calm night; hence an entertainment of music given by a lover to his mistress under her window. Serenading has been chiefly practised in Spain and Italy. It is common among the students of the German universities to assemble at night under the window of a favourite professor, and give him a musical tribute.—A piece of music characterised by the soft repose which is supposed to be in harmony with the stillness of night, is called a serenade, or sometimes a *Notturno*.

SERE'TH, an important affluent of the Danube, rises in the Austrian crownland of Galicia, becomes for some distance the boundary between Moldavia and Wallachia, and joins the Danube 5 miles above Galatz, after a course of 300 miles.

SERF (Lat. *servus*, a slave). A numerous class of the population of Europe known as serfs or villeins, were in a state of slavery during the early middle ages. In some cases, this serf population consisted of an earlier race, who had been subjugated by the conquerors; but there were also instances of persons from famine or other pressing cause selling themselves into slavery, or even surrendering themselves to churches and monasteries for the sake of the benefits to be derived from the prayers of their masters. Different as was the condition of the serf in different countries and at different periods, his position was on the whole much more favourable than that of the slave under the Roman law. He had certain acknowledged rights—and this was more particularly the case with the classes of serfs who were attached to the soil. In England, prior to the Norman Conquest, a large proportion of the population were in a servile position, either as domestic slaves or as cultivators of the land. The name of *nativus*, generally applied to the serfs, seems to indicate that they belonged to the native race, the earliest possessors of the soil. The powers of the master over his serf were very extensive, their principal limitations being, that a master who killed his serf was bound to pay a fine to the king, and that a serf deprived of his eye or tooth by his master was entitled to his liberty. The Norman Conquest made little change in the position of the serf. The lowest class of serfs were the *villeins in gross*, who were employed in menial household services, and were the personal property of their lords, who might sell them or export them to foreign countries; while the most numerous class, who were employed in agriculture, and attached to the soil, were called *villeins regardant*. These latter, though in some respects in a better position than the villeins in gross, might be severed from the land, and conveyed apart from it by their lord. They were incapable of enjoying anything like a complete right to property, inasmuch as it was held, in accordance with the principles of the Roman law, that whatever the slave acquired was his *peculium*, which belonged to his lord, who might seize it at his pleasure. By a peculiarity in the usages of Britain, the condition of a child as regards freedom or servitude followed the father, and not the mother, and therefore the bastards of female villeins might be free. In France and Germany, besides the classes of serf alluded to, there were others whose servitude was of a milder description, and who were only bound to fixed duties and payments in respect of their lands.

The abolition of serfdom in Western Europe was a very gradual process, various causes having combined to bring it about. The church both inveighed against the practice of keeping Christians in bondage, and practised manumission to a large extent. In the course of time, usage greatly modified the rights and liabilities of the serf, whose position must have been considerably altered when we find him making stipulations regarding the amount of his services, and purchasing his own redemption. The towns afforded in more than one way a means of emancipation. A serf residing a year in a borough without challenge on the part of his lord, became *ipso facto* a free man; and the result of experience shewed that the industry of the free labourer was quite as productive as that of the serf. At all events, serfdom died out in England without any special enactment; yet it was not wholly extinct in the latter half of the 16th c., for we find a commission issued in 1574 by Queen Elizabeth, to inquire into the lands and goods of all her bondsmen and bondswomen in the counties of Cornwall, Devon, Somerset, and Gloucester, in order to compound with them for their manumission, that they might enjoy all their lands and goods as freedmen. In a few rare instances, liability to servile duties and payments in respect of lands seem to have continued down to the reign of Charles I. In Scotland, as in England, serfdom disappeared by insensible degrees; but a remarkable form of it continued to survive down to the closing years of last century. Colliers and salters were bound by the law, independent of paction, on entering to a coal-work or salt-mine, to perpetual service there; and in case of sale or alienation of the ground on which the works were situated, the right to their services passed without any express grant to the purchaser. The sons of the collier and salter could follow no occupation but that of their father, and were not at liberty to seek for employment anywhere else than in the mines to which they had been attached by birth. Statutes 15 Geo. III. c. 28 and 39 Geo. III. c. 56, restored these classes of workmen to the rights of freemen and citizens, and abolished the last remnant of slavery in the British islands.

In France, though a general edict of Louis X., in 1315, purported to enfranchise the serfs on the royal domain on payment of a composition, this measure seems never to have been carried into effect, and a limited sort of villeinage continued to exist in some places down to the Revolution. In some estates in Champagne and Nivernais, the villeins, known as *gens de main morte*, were not allowed to leave their habitations, and might have been followed by their lords into any part of France for the *taille* or villein-tax. In Italy, one great cause of the decline of villeinage was the necessity under which the cities and petty states found themselves to employ the peasant population for their defence, whom it became expedient to reward with enfranchisement. In the 11th and 12th centuries, the number of serfs began to decrease, and villeinage seems no longer to have had an existence in Italy in the 15th century. Over a large portion of Germany, the mass of the peasants had acquired their freedom before the end of the 13th c., but in some parts of the Prussian dominions a modified villeinage continued to exist until swept away by the reforms of Von Stein in the present century.

In Russia, where the feudal system never prevailed, the early condition of the peasant was not a servile one. Down to the 11th c., he could occupy any portion of the soil that he had the means of cultivating, the land being the property of all, and

farmed on the purest communistic principles. The reduction of the peasantry to a state of serfdom, and their attachment to the soil, was gradually effected, and not completed till the close of the 16th century. The Russian peasant of the 19th c. was in some respects in as servile a condition as the feudal villein of the 12th c. in the west of Europe; but there was this peculiarity attaching to his position, that while he himself was the property of his lord, the land which he cultivated belonged to himself—a consideration which greatly complicated the question of his emancipation. The Emperor Alexander I. introduced various improvements in the condition of the peasantry, particularly those belonging to the crown, and in his reign serfdom was abolished in Courland and Livonia. The entire abolition of villeinage has been effected by the present emperor, Alexander II., by a very sweeping measure. From March 1863, the peasants, both husbandmen and domestics, have been made entirely free as regards their persons, while they have also obtained the perpetual usufruct of their cottages and gardens, and certain portions of land.—See, on the subject of serfdom generally, Hallam's *State of Europe during the Middle Ages*, chap. 2.

SERGE, a kind of twilled worsted cloth of inferior quality. There is also a coarse kind of twilled silk used for lining gentlemen's coats called silk serge.

SE'RGEANTS in the British army are non-commissioned officers of the army and marines in the grade next above corporal, whose duties are to overlook the soldiers in barracks, and to assist the officers in all ways in the field. Every company has four sergeants, of whom the senior is the colour-sergeant. A superior class are the staff-sergeants, as the quarter-master-sergeant, armourer-sergeant, hospital-sergeant; and above them all is the sergeant-major. See NON-COMMISSIONED OFFICERS. In the army of the United States the sergeant-major of engineers receives $36 per month; a sergeant-major of cavalry, artillery, and infantry, $21 per month. There are also officers known as quartermaster-sergeant of engineers and of cavalry, a first sergeant of cavalry, company quarter-master-sergeant of engineers and ordnance, and sergeant of cavalry. Each regiment has 1 sergeant-major and 1 quarter-master-sergeant, while in the minimum organisation of the regiments 6 sergeants are awarded to each mounted, and 4 to each company not mounted.

SE'RGEANTY, GRAND (Fr. *sergenterie*, from Lat. *serviens*), a tenure by which lands were held in feudal times in England. After the Conquest, the forfeited lands were parcelled out by William to his adherents on condition of the performance of services of a military character. The military tenants of the crown were, however, of two descriptions: some held merely *per servicium militare*, by knight-service; others held *per sergentiam*, by grand sergeanty, a higher tenure, which involved attendance on the king not merely in war, but in his court at the three festivals of the year, and at other times when summoned. Although the word baron, in its more extended sense, was applied to both classes of crown tenants, yet it was only those holding by grand sergeanty whose tenure was said to be *per baroniam*. In its earliest stage, the distinction between the greater nobility and lesser nobility or gentry in England was, that the former held by grand sergeanty, and the latter by knight-service only. In theory, lands held by sergeanty could not be alienated or divided; but practically this came to be often done, and by this means tenures by sergeanty became gradually extinct before the abolition of military holdings. Considerable misapprehension on the part of Dugdale and later writers has arisen from a double use of the word *serviens*, or sergeant, which is sometimes applied to a tenant either by grand sergeanty or knight-service who had not taken on himself the obligations attendant on knighthood.

The term petty sergeanty was applied to a species of socage tenure in which the services stipulated for bore some relation to war, but were not required to be executed personally by the tenant, or to be performed to the person of the king, as the payment of rent in spurs or arrows.

SERGI'PÉ, a maritime province of Brazil, bounded on the N. by the São Francisco, which separates it from Alagoas; on the W. and S. by Bahia; and on the E. by the Atlantic. According to the most recent statements, this province is the smallest in the empire. Area, 11,088 sq. m.; pop. 183,600. The shores are low and sandy, the interior mountainous. The east part is fertile, well wooded, and produces sugar and tobacco; the western districts are devoted principally to the rearing of cattle. The chief town is Sergipe del Rey, at the mouth of the chief river—the Vasa Barris—and with a pop. stated at 9000.

SERINAGU'R, SIRINUGGUR, or CASHMERE, the capital of the valley of Cashmere, stands on both sides of the Jhelum, which is here 100 yards wide, 170 miles north-north-east of Lahore. It is quaint and picturesque-looking almost beyond conception. The streets, or rather narrow lanes, lead to the river, and the houses, five and six stories high, are built of wood. Not a single straight line is to be seen. The houses overhang the river, and lean towards each other above the lanes in various stages of dilapidation. Communication between the two quarters is kept up by means of a number of rustic wooden bridges, built on enormous piles of timber. Shawls are an important article of manufacture (see CASHMERE). The manufacture of articles of papier-mâché, the designs of which are far in advance of the workmanship, and engraving on stone and metal, are also important branches of industry. The vicinity of the city, with its border of towering mountains, is exceedingly beautiful. The numerous lakes, connected with the town and river by canals, recall Venice to the traveller. The most notable public structures are the Jumna Musjid or 'Great Mosque,' capable, according to native estimate, of containing 60,000 persons, the mosque of Shah Hamedan, a royal tomb, and the governor's residence. Near the east end of the city lies the dal or Lake of Serinagur, about 5 miles long, and 2½ broad. It is a lovely and tranquil sheet of water, was formerly a choice retreat of the Mogul emperors, the remains of whose pleasure-grounds and palaces are still visible on its margin, the most celebrated being the Shalimar, of polished black marble. Pop. estimated at 40,000; in the early part of the present century, it is stated to have been from 150,000 to 200,000.—*Captain Knight's Diary of a Pedestrian in Cashmere and Tibet* (1863).

SERINGAPATA'M (properly, *Shri Ranga Patanam*, City of Vishnu), a decayed city of Southern India, built on an island in the channel of the Kaveri, nine miles north-north-east of Maisur. The island, three miles long, and one mile broad, has a wretched appearance, and the town itself is ill-built, ill-ventilated, and ugly. The fort, about three-quarters of a mile broad, is surrounded by strong walls of stone, and contains the palace of Tipu Sahib (q. v.). In the days of its highest prosperity, S. is said to have contained 300,000 inhabitants; in 1800, it contained 31,895, and now it contains little over 12,000. Hyder Ali (q. v.) made it the seat of his government in 1765. It was besieged by Lord

Cornwallis in 1791, and again in 1792. On the last occasion, the terms dictated by the commander of the British to Tipu, the son and successor of Hyder Ali, were very severe. A British army appeared before the walls again in 1799; and on the 3d May of that year, the fort was stormed, and Tipu slain in the vicinity of his own palace.

SERJEANT-AT-ARMS, in the English Court of Chancery, is the officer who attends upon the Lord Chancellor with the mace, and who executes by himself or deputies various writs of process directed to him in the course of a Chancery suit. A similar officer attends on the Senate and House of Representatives of the United States, and on each House of Parliament, and arrests any person ordered by their authority to be arrested.

SERJEANT-AT-LAW used to be the highest degree of barrister in the common law of England, and was called serjeant-counter, or of the coif. The degree is of great antiquity, and formerly a barrister could only be appointed after being of sixteen years' standing, but now no particular qualification as to time is required. Formerly, also, they had exclusive audience in the Court of Common Pleas, but that monopoly has been abolished. The proper forensic dress of a sergeant is a violet-coloured robe with a scarlet hood. A serjeant is appointed by a writ or patent of the crown. The Chief Justice of the Common Pleas recommends the barrister to the Lord Chancellor, who advises the crown to make the appointment. The degree of serjeant is entirely honorary, and merely gives precedence over barristers; and when he is appointed, he is rung out of the Inn of Court to which he belongs, and thereafter joins the brotherhood of Serjeants, who form a separate community. By ancient custom, the common law judges are always admitted to the order of serjeants before sitting as judges, and hence they always address a sergeant as a brother. A Queen's Counsel (q. v.) takes precedence of all serjeants, unless these have patents of precedence, which prevent them being displaced by the Queen's Counsel who come after them. Sometimes one or more of the serjeants are appointed Queen's Serjeants.

SEROUS FLUIDS. This term is applied by chemists and physicians to various fluids occurring in the animal body. They are arranged by Gorup-Besanez, one of the highest authorities on Physiological Chemistry, under three heads: 1. Those which are contained in the serous sacs of the body, as the cerebro-spinal fluid, the pericardial fluid, the peritoneal fluid, the pleural fluid, the fluid of the tunica vaginalis testis, and the synovial fluid. 2. The tears and the fluids existing in the eyeball, the amniotic fluid, and transudations into the tissue of organs. 3. Morbid or excessive transudations, such as dropsical fluids, the fluids occurring in hydatids, and in blebs and vesicles on the skin, and transudations from the blood in the intestinal capillaries, as in cases of intestinal catarrh, cholera, or dysentery.

All these fluids bear a close resemblance to one another, both in their physical and chemical characters. In so far as relates to their physical characters, they are usually clear and transparent, colourless or slightly yellow, of a slight saline, mawkish taste, and exhibiting an alkaline reaction with test-paper. They possess no special formal or histological elements, but on a microscopic examination, blood-corpuscles, cells of various kinds, molecular granules, and epithelium may occasionally be observed in them. The ordinary chemical constituents of these fluids are water, fibrin (occasionally), albumen, the fats, animal soaps, cholesterin, extractive matters, urea (occasionally), the same inorganic salts which are found in the serum of the blood, and the same gases as occur in the blood. As rare constituents, and only occurring in disease, may be mentioned sugar, the biliary acids, salts of lactic and succinic acids, creatinine, mucin, &c. The following analyses of four of these fluids will serve to give a good idea of their composition:

	Plasma of the Blood.	Peritoneal Dropsy.	Hydrothorax.	Dysenteric Transudation.
Water,	901·51	946·0	936·0	958·6
Solid Constituents,	98·49	54·0	64·0	41·4
Fibrin,	8·06		0·6	
Albumen,	81·92	33·0	52·8	15·0
Extractive Matters,		13·0	3·0	14·6
Inorganic Salts,	8·51	8·0	7·4	11·8

SEROUS MEMBRANES. There are seven of these membranes in the human body, three being median and single, while two are double and lateral. They are the arachnoid, the pericardium, and the peritoneum, with the two pleuræ and tunicæ vaginales testis. Thus they are connected, with the obvious view of facilitating motion and affording general protection, with all the most important organs in the body. They are all closed sacs, with one exception, and a reference to the articles PERICARDIUM, PERITONEUM, and PLEURÆ, will at once shew the reader that each sac or continuous membrane consists of two portions—a parietal one, which lines the walls of the cavity, and a visceral, or reflected one, which forms an almost complete coating or investment for the viscera contained in the cavity. The interior of the sac is filled during life with a halitus or vapour, which after death condenses into a serous fluid. With regard to their structure, it is sufficient to state that they consist essentially of (1) Epithelium; (2) Basement Membrane; (3) A stratum of areolar or cellular tissue, which constitutes the chief thickness of the membrane, and is the constituent on which its physical properties are mainly dependent. This layer is more liable to variation than the others, and one of the most common alterations is an augmentation of the yellow fibrous element, by which an increased elasticity is given to the membrane, which is thus better adapted for distention, and for a subsequent return to its original bulk. The situations in which this augmentation is found are, as Dr Brinton (*Cyclopædia of Anatomy and Physiology*, vol. iv. p. 524) has pointed out, in exact conformity with this view: in the peritoneum, which lines the anterior abdominal wall, and covers the bladder, it attains its maximum; in the detached folds of the mesentery, in the costal pleuræ, and in the suspensory ligament of the liver, it is still very prominent; while on the posterior wall of the belly, and in serous membranes covering the heart, liver, &c., it is almost absent.

The following are the most important of the morbid changes to which these membranes are liable. One of the most frequent of the morbid appearances seen in these structures is the presence of an excess of serous fluid in their cavity. This condition occurs in deaths from various diseases, and in general the serous membrane only shares in a dropsy which is common to other structures, and especially affects the areolar or cellular tissue. When general anasarca, or dropsy of the cellular tissue, has existed for a long time, more or less dropsical effusion is usually found in the pleuræ and peritoneum. The inflammation of these structures is sufficiently described in the articles PERICARDITIS, PERITONITIS, and PLEURISY. Tubercle is seldom primarily deposited in these membranes, although it is not uncommon after other organs have been implicated. Cancer and ossification of the serous membranes are rare affections, but cysts

of various kinds, some of which are of parasitic origin, are often found.

Synovial membranes present many points of similarity to serous membranes; as, however, they also present several points of difference, they will be briefly noticed in a special article.

SERPENT, a powerful bass musical wind instrument, consisting of a tube of wood covered with leather, furnished with a mouthpiece like a trombone, ventages, and keys, and twisted into a serpentine form, whence its name. Its compass is said to be from B♭ below the bass staff to C in the third space of the treble clef, including every tone and semitone—  , but the highest octave does not sound well with ordinary players. When unskilfully played, it exhibits the most startling inequalities of tone, in consequence of there being three notes  much more powerful than the rest. The serpent is in B♭, and therefore music for it must be written a whole tone above the real sounds. The serpent was invented by a French priest at Auxerre in 1590, and while its principal use has been in military music, it has also been employed in the orchestra to reinforce the basses. As an orchestral, and even as a military instrument, the serpent is far less manageable than the Ophicleide (q. v.), which has nearly superseded it. It is still much used in the music of the Roman Catholic Church.

SERPENTA'RIA. See ARISTOLOCHIA.

SERPENT-CHARMING, an art which has been practised in Egypt and throughout the East from remote antiquity, and which forms the profession of persons who employ it for their own gain, and for the amusement of others. In India, and partly if not entirely in other countries, this profession is hereditary.

There are several allusions to serpent-charming in the Old Testament: see Psalm lviii. 4, 5; Eccles. x. 11; Jer. viii. 17. It is mentioned also by some of the ancient classics, as Pliny and Lucan.

Serpent-charmers usually ascribe their power over serpents to some constitutional peculiarity, and represent themselves as perfectly safe from injury even if bitten by them. To confirm this, they are accustomed, in their exhibitions, to exasperate the serpents, and allow themselves to be bitten, so that blood flows freely. But it has been fully ascertained that the serpents which they carry with them, and produce on these occasions, although of the most venomous kinds, have been at least deprived of their poison-fangs, and to prevent new ones from growing, a portion of the maxillary bone is often if not always taken out; in some cases, it appears that the poison-glands themselves are removed by excision and cautery.

So much, however, being set aside as of the nature of a mere juggler's trick, much still remains which is interesting, and in which there is unquestionable reality. The serpent-charmers of the East have a power beyond other men of knowing when a serpent is concealed anywhere, long practice having probably enabled them to distinguish the musky smell which serpents very generally emit, even when it is too faint to attract the attention of others. They are therefore sometimes employed to remove serpents from gardens and the vicinity of houses. In this, as in their exhibitions, they pretend to use spells. What power the tones of their voice may exert, is of course uncertain; but they accompany their words with whistling, and make use also of various musical instruments, the sound of which certainly has great power over serpents. When they issue from their holes, the serpent-charmer fearlessly catches them, by pinning them to the ground by means of a forked stick. But one of the first things he does afterwards is to knock out or extract the poison-fangs.

In the exhibitions of serpent-charmers, the creatures are often made to twine round the bodies of the performers. They also erect themselves partially from the ground, and in this posture they perform strange movements to the sound of a pipe, on which the serpent-charmer plays. It appears also that he exerts a very remarkable influence over them by his eye, for even before any musical sound has been employed, he governs and commands them by merely fixing his gaze upon them.

In 1850 a party of Arab serpent-charmers visited London, where exhibitions took place similar to those which are common in the East.

SE'RPENTINE, a mineral, composed of silica and magnesia in almost equal proportions, with about 13—15 per cent. of water, and a little protoxide of iron. S. is generally massive; very rarely crystallised in rectangular prisms. COMMON S. sometimes occurs as a rock. It is unctuous to the touch, and soft enough to be scratched by calcareous spar. It is not easily broken, but can be cut without much difficulty. It is generally green, black, or red; the colour sometimes uniform, sometimes spotted, clouded, or veined. It receives its name from its mottled appearance, resembling the skin of a serpent. It is cut and turned into ornaments of various kinds. PRECIOUS S., or NOBLE S., is of a rich dark-green colour, hard enough to receive a good polish, translucent; and sometimes contains embedded garnets, which form red spots, and add much to its beauty. It is a rather rare mineral. It occurs at Baireuth in Germany, in Corsica, at Portsoy in Banffshire, and in many places in the United States. It is generally found along with foliated limestone, in beds under gneiss, mica-slate, &c., or in Common Serpentine. The ancient Romans used it for pillars and for many ornamental purposes; and vases, boxes, &c. are still made of it, and much prized. The ancients ascribed to it imaginary medicinal virtues.

S. belongs to the metamorphic rocks. It occurs as an irregularly overlying mass in the Lizard district of Cornwall, as a dyke at Portsoy, in the Barren Hills of Chester County, Pennsylvania, and in Maryland, &c. It is generally associated with the granitoid, igneous, or metamorphic rocks, though it is occasionally found as a member of the trappean series. Trap dykes, in passing through or coming into contact with limestone, not unfrequently convert it into serpentine, or fill it with lines or masses of serpentine.

SERPENTS (*Ophidia*), an order of Reptiles, which is in general simply characterised as having a very elongated body and no external limbs. The links, however, which unite saurians with serpents are very numerous; the limbs of many saurians being partially wanting, and little more than rudimentary; whilst rudimentary limbs are found by anatomical examination in many serpents, and the rudimentary hinder limbs of some, as boas, appear externally in the form of hooks or claws. See BOA.

The body and tail are covered with scales, the head often with plates. The vertebræ and ribs are extremely numerous, a pair of ribs being attached to each vertebra throughout the whole length of the body. Some serpents have more than 300 pair of ribs. The ribs not only serve to give form to the body, and aid in respiration, but are also organs

of locomotion. There is no breastbone (*sternum*) for the small end of the ribs to be attached to, as in other vertebrate animals, but each rib is joined by a slender cartilage and a set of short muscles to one of the scales of the abdomen. A serpent moves

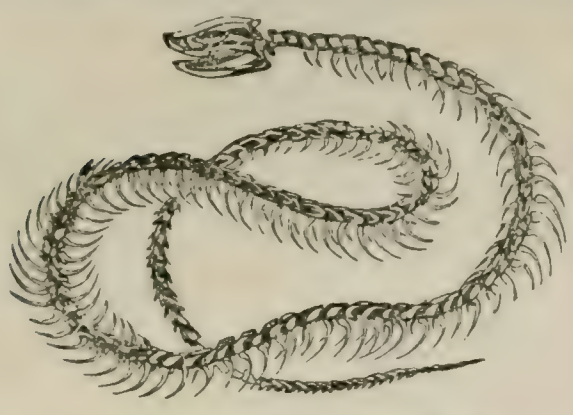


Fig. 1.—Skeleton of the Rattlesnake.

by means of the ribs and of these scales, which take hold on the surface over which it passes, and in this way it can glide—often very rapidly—along the ground, or on the branches of trees; and many species climb trees with great facility, gliding up them as if on level ground. Most—if not all—of the species are also capable of elevating a great portion of the body from the ground; and many of those which live among the branches of trees hold their place firmly by means even of a few scales near the tail, and freely extend the greater portion of the body in the air. On a perfectly smooth surface, as that of glass, a serpent is quite helpless, and has no power of locomotion.

The vertebræ of serpents are so formed as to admit of great pliancy of the body, which is capable of being coiled up, with the head in the centre of the coil, and some serpents have the power of throwing themselves to some distance from this coiled position. The vertebræ are articulated by perfect ball-and-socket joints, the anterior extremity of each being rounded into a smooth and polished ball, which fits exactly into a hemispherical cup in the next; but there are processes in each vertebra which prevent any motion except from side to side, so that serpents are quite incapable of the vertical undulations so often represented in prints. The ribs are also attached to the vertebræ by ball-and-socket joints.

Müller laid the basis of a true system of the *Ophidia*, and Duméril and Cope have added most of what is known of it at the present time. The first divided them into two groups based on the relation of the opistotic bone to the cranium; in one it forms part of the walls of the latter, in the other is merely adherent externally and supports the under jaw. Of the first there are two prominent divisions: 1. *Scolecophidia*, without ectopterygoid or teeth on the maxillary bone, embracing the *Typhlophidæ* and *Stenostomidæ;* and 2. *Tortricina*, where both ectopterygoid bone and maxillary teeth are present; here are the families *Uropeltidæ* and *Tortricidæ*. All have rudimental hind limbs, except the *Uropeltidæ*. All the preceding, except the *Tortricidæ*, are entirely subterranean, and the *Uropeltidæ* is almost confined to the island of Ceylon. The others occur in all tropics. The wide-mouthed snakes have the maxillary bone either long and slender or short and elevated, for the support of venom-fangs. Those of the former division are called the *Asinea*, and are more numerous than those of any other. They are arranged according to the presence or absence of the coronoid bone and rudimental hind limbs. Those with both are the *Xenopeltidæ*, *Pythonidæ*, *Boidæ*, and *Lichanuridæ*. Those without either are much the most numerous, the largest family being the *Colubridæ*. The latter are spread over the whole world. There are two divisions of those with jaw-bone altered for venom-fangs, those where it is shortened in front only (*Proteroglypha*), and those where it is so shortened at both ends as to be vertical. Of the former are the flat-tailed sea-snakes and the round-tailed Cobras (*Najidæ*) and *Elapidæ*. Many of this division have harmless teeth behind the venom-fangs, and the latter are always short. Of the higher venomous serpents (*Solenoglypha*) there are four families, of which the *Viperidæ* (vipers) and *Crotalidæ* (rattlesnakes) are best known.

The True Serpents live on larger prey, which they swallow entire, some of them—as the boas—crushing it by constriction in the coil of their muscular body. The prey of a serpent is often thicker than the serpent itself, and to admit of its being swallowed, the throat and body are very dilatable. The bones of the head are adapted to the necessity of a great expansion of the mouth and dilation of the throat, as will be seen by the annexed figure of the distended jaws of the rattlesnake. The bones composing the upper jaw are loosely joined together by ligaments; and even the arches of the palate are movable. The two halves of the lower jaw are connected by a ligament, so loose and elastic that they are capable of separation to a great extent; and the mastoid and tympanic bones, which connect the lower jaw and the skull, are lengthened out into pedicles, allowing an extraordinary power of dilation. Serpents, however, sometimes seize prey too big for them to swallow, and die in the attempt, their teeth being so formed as to prevent them from rejecting by the mouth what has once got into the throat.

Fig. 2.

The teeth of the True Serpents are simple, and directed backwards. In the non-venomous kinds, there are four rows on the upper part of the mouth, two rows on the jaws, and two on the palate; each division of the lower jaw is also armed with a single row. In vipers, rattlesnakes, and other venomous serpents, there are no teeth on the upper jaw, except the poison-fangs; the palatal teeth, however, forming two rows as in the non-venomous kinds, the arrangement of teeth in the lower jaw being also the same. Venomous serpents do not, in fact, need the same array of teeth as the non-venomous; depending rather on the power of their venom for their prey, which they suddenly wound, and then wait till it is dead. The poison-fangs are long in comparison with the other teeth; they are two in number, firmly fixed into a movable bone; when not in use, they are laid flat on the roof of the mouth, covered by a kind of sheath formed by the mucous membrane of the palate; when the animal is irritated, and about to assail its enemy or its prey, they stand out like two lancets from the upper jaw. They move with the bone into which they are fixed; and the bone and muscles are so arranged that the opening of the mouth brings them into the position for use. There is above them, and towards the back of the head, a large gland for the elaboration of the poison, which is forced through them by the action of the muscles.

each fang being tubular. The tube of the fang is formed, not as by a hollowing of it, but as by a bending of it upon itself, and is situated in front. The opening at the point of the fang is a narrow longitudinal fissure. The poison-fangs are very liable to be destroyed, and the germs of new ones are generally found behind them, ready to grow and supply their place.

It is sometimes stated as a distinction between venomous and non-venomous serpents, that the former have only two rows of teeth on the upper part of the mouth, whilst the latter have four. This rule must not, however, be accepted without qualification. In the marine serpents (*Hydridæ*), there are rows of maxillary teeth behind the poison-fangs; and some of the venomous land-serpents, as the Bongars or Rock Snakes of the East Indies, which, however, are not amongst the most venomous, have some smaller teeth in the jaw-bones behind the poison-fangs.

The venom of serpents differs very much in its deadly power in different species. The bite of some causes the death of a human being in a few minutes, so that no creatures are more formidable; that of others proves fatal after the lapse of hours; whilst the bite of others, such as the common viper, is seldom fatal, although causing great pain and many unpleasant consequences. 'I have carefully examined all the evidence on record,' says Mr Buckland, 'as regards the most efficacious internal remedy that can be given in such cases, and have come to the conclusion that nothing is so good as ammonia' (*Curiosities of Natural History*). The same writer also recommends brandy or other stimulating drinks to be taken in large quantities. But it is of the utmost importance to suck the wound as soon as possible after it has been inflicted, and no danger is to be apprehended in doing so, if there be no scratch or sore about the mouth, for the poison, so deadly when it mixes with the blood, is quite innocuous when taken into the stomach.

Many antidotes to the poison of serpents are in vogue in different countries, most of them, if not all, utterly unworthy of regard. But a method employed in India, by those who collect cobras for the exhibition of serpent-charming, seems to deserve notice: it is the prompt application to the wound of certain balls, which probably act by absorbing the poisoned blood, and extracting it from the wound. What these balls are made of, is not yet well known, though they are said to have the appearance of bone that has passed through great heat. Their absorbent power is certainly great.

The peculiarities of the lungs of serpents are noticed in the article Reptiles. The heart is placed very far back in the body. The intestines have a great absorbent power, and the fæces consist only of the most indigestible portions of the prey in an extremely desiccated state; the members of the animal which has been swallowed being still often distinguishable, and hair, scales, and the like remaining unchanged.

The tongue of serpents is forked, and is often thrust out of the mouth. It is vulgarly regarded as the *sting*, but serpents have no sting, their only weapons being the fangs already noticed. The only sound which serpents emit is that of hissing.

Serpents are either strictly oviparous or they are ovoviviparous. The non-venomous serpents are generally oviparous; the venomous, ovoviviparous. The eggs of those which lay eggs are generally deposited in a long string, connected by a kind of viscous substance, in some heap of decaying vegetable matter, the mother paying no further heed to them. But some serpents coil themselves around their eggs and hatch them; and it would even seem that the habits of the same species differ as to this, in different climates. The eggs of serpents are not quite devoid of calcareous covering, but have so little that their integument is soft and pliable.

It has been often alleged that vipers and other serpents, when alarmed, swallow their young, and eject them again after reaching a place of safety. There still remains some doubt on this curious question, which has recently been much discussed; and it is not improbable that the alleged proofs of it from living young ones issuing out of the body of the parent when crushed, are to be accounted for by the ovoviviparous mode of generation.

It seems probable that serpents do not possess the senses of taste or smell in great perfection. The ear has no external opening, and no tympanum, nor is it certain that their hearing is acute, but they are remarkably sensible of the power of music, of which serpent-charmers avail themselves, both to bring them from their holes and to control them. See Serpent-charming. A European gentleman, residing in one of the mountainous parts of India, found that his flute attracted them in such numbers to his house that he was under the necessity of ceasing to play it. Their eyes are small, and are protected from the dangers to which they might otherwise be exposed, by a transparent integument connected with the skin, and which comes away with the skin when the old skin is cast off, as is the case at least once a year.

The colours of serpents are very various, and often very beautiful. As a general rule, but not without exceptions, the venomous species are of darker and more uniform colour than the non-venomous. The aversion and horror with which serpents are so generally regarded, are of course due to the dangerous character of so many of them, and the difficulty of observing and avoiding them.

Serpents are used as food by some savage tribes. They are capable of being tamed, and some of the non-venomous species have frequently been so, and have been found useful in killing mice, rats, and other such vermin.

Serpents abound chiefly in tropical climates, although some are found in northern countries, as in Scandinavia. In the United States there are 123

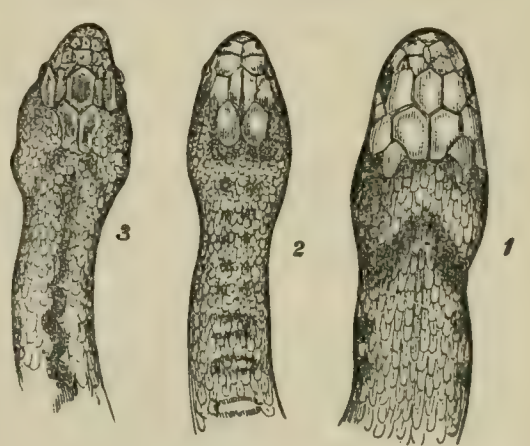

Fig. 3.
1, European Ring Snake; 2, Coronella lævis; 3, Viper.

species of S., of which only 20 are venomous. Of these, 14 are rattlesnakes, 3 moccasins, and 3 *elapes*. The last are little venomous.

SERPUKO'V, a very ancient Russian town, 56 miles south of Moscow, close to the left bank of the Oka. It contains a cathedral, and is defended by a Kreml, or citadel. There are upwards of 50 factories, of which those engaged in the manufacture of sail-cloth, woollen goods, and leather are of importance. Pop. about 15,000.

SE'RPULA, a genus of Annelida, of the order *Tubicola*, forming and inhabiting a calcareous tube, like that of molluscs, and therefore described in old works on conchology. Indeed, the shell of a S. is not always easily distinguished from that of molluscs of the genus *Vermetus*, although the inhabitants are extremely different; but the shell of *Vermetus* has a regular spire at the apex, which is not found in that of any serpula. The serpulæ attach their shells to rocks, shells, &c. in the sea. The shell is variously contorted, and some of the species live in groups,

Serpula Contortuplicata.

with the shells intertwined. The wider end of the shell is open, and from it the animal protrudes its head and gills, which expand as beautiful fan-like tufts. They are in general exquisitely coloured, and serpulæ are among the most interesting and beautiful creatures that can be placed in an aquarium. On the slightest alarm, they disappear completely into the tube, which then is closed by an operculum curiously framed as an appendage to the gills. Several species of S. are common on the British coasts, but the largest are found in tropical seas, and are among the many lovely objects to be seen in looking down through clear still water on coral reefs.

SERRAVA'LLÉ, a city of Northern Italy, in Venetia, on the river Aleschio, 35 miles north of Venice. It is situated in a valley, and was formerly fortified. The cathedral S. Andrea is very ancient. Pop. 5714.

SERTO'RIUS, Q., one of the ablest Roman commanders in the later ages of the Republic, was a native of Nursia, in the country of the Sabines, and began his military career in Gaul. He fought, 105 B. C., in the disastrous battle on the Rhone in which the Roman proconsul, Q. Servilius Cæpio, was defeated by the Cimbri and Teutones, and took part in the splendid victory at Aquæ Sextiæ (mod. Aix), 102 B. C., where Marius annihilated the same barbarians. On the breaking out of the sanguinary struggle between the party of the nobles under Sulla (q. v.) and the popular party headed by Marius (q. v.) (88 B. C.), he espoused the cause of the latter. Morally, he was much superior to the military adventurers of his time; and the impression we have of him from Plutarch's picturesque biography is that of a valiant, resolute, honest, and stubborn Roman, such as was commoner in the 3d than in the 5th c. of the Republic. None of the Marian generals held out so long or so successfully as he against the victorious oligarchy. He fought in conjunction with Cinna the battle at the Colline Gate, which placed Rome at the mercy of the Marians, but he had no hand in the bloody massacres that followed. What we do hear of him is to his credit. He got his own troops together, and slew 4000 of the ruffianly slaves whom Marius was permitting to plunder and ravish at will through the city. On the return of Sulla from the East (83 B. C.), S. withdrew into Etruria, but finding it impossible to act in concert with the other military leaders of his party, he went to Spain, where he continued the struggle in an independent fashion. At first he was not very successful, and found it advisable to embark for Mauritania. After several adventures, in the course of which he once passed through the Strait of Gibraltar, and fell in with some sailors who had visited the Atlantic islands, and whose descriptions so wrought upon his imagination, that he 'was seized with a strong desire to dwell in the islands, and to live in quiet, free from tyranny and never-ending wars'—(Plutarch)—he returned to the Peninsula, at the invitation of the Lusitanians, got together an army composed of natives, Libyans and Romans, and after a time became the virtual monarch of the whole country. During 80—76 B. C., he was victorious over all his opponents, nor was it until the arrival (76 B. C.) of young Pompey ('Pompey the Great'), that he found an opponent worthy to cope with him; and even Pompey was scarcely yet his equal in military skill. S. drove Pompey over the Iberus (Ebro) with heavy loss; nor was the campaign of the following year (75 B. C.) more favourable, for though S.'s subordinates were twice beaten, Pompey himself had no success, and was forced to write urgent letters to the senate for reinforcements. The campaigns of the next two years were unimportant, except in so far as they shew us the gradual operation of that miserable jealousy and envy of S. that brought about his ruin. Perperna, and other Roman officers of the Marian party, who had fled to him in 77 B. C., when Sulla became triumphant at home, and who seem to have been a set of base adventurers, secretly stirred up the Spaniards against him, and when that artifice did not prove so successful as was hoped, they conspired against his life, and assassinated him in his own tent, 72 B.C., under circumstances of shameful perfidy. With S. the Marian or popular cause sunk, until it was revived and attained final success in the person of Julius Cæsar (q. v.). Plutarch has written S.'s life, and Corneille has made it the subject of a tragedy.

Sertularia Ingra, with a portion magnified.

SERTULA'RIA, a genus of zoophytes (*Anthozoa*), plant-like and branched, horny, tubular, filled with a semi-fluid organic pulp, the polype cells in two rows on the branches, the polypes hydra-like. The species are numerous, and some are common on the British coasts, attached to stones, shells, sea-weeds, &c. The sertulariæ are very beautiful.

SE'RUM. See BLOOD.

SE'RVAL (*Felis Serval* or *Leopardus Serval*), one of the smaller *Felidæ*, a native of South Africa, the *Boschkatte*, or Bush-cat, of the Cape Colony. It is about two feet in length, exclusive of the tail. The S. is a beautiful animal, yellowish with black

Serval (*Felis Serval*).

spots, the lower parts white with black spots. The fur of the S. is in great request, and is known to furriers as that of the *Tiger Cat*. The S. is one of the mildest and most docile of the *Felidæ*.

SERVANT. See MASTER AND SERVANT.

SERVETUS, MICHAEL, or, in his native Spanish, MIGUEL SERVEDE, a notable and unfortunate speculator in theology, was born at Villanueva, in Aragon, in 1509. At the age of nineteen, he quitted Spain, and commenced the study of law at Toulouse, which he soon abandoned to devote himself with ardour to the knotty points of the Reformation doctrines. In 1530, he went to Basel to hear Œcolampadius, and thence to Strasburg, where Bucer and Capito taught. His daring denial of the doctrine of the Trinity frightened or angered these divines to such a degree that they denounced him as 'a wicked and cursed Spaniard.' S. appealed from their judgment to that of the public in his *De Trinitatis Erroribus Lib. VII.* (Haguenau, 1531; modern edition, Nürnberg, 1791), and his *Dialogues* (Haguenau, 1532); but the public thought as little of his teaching as the theologians; and to avoid the odium which it had occasioned, he changed his name to Michael de Villanueva, and fled to Paris, where he studied medicine under Sylvius and Fernel, and took his degree as a physician with honours. S. seems to have possessed a kind of penetrating, if also rash and restless intellect, which enabled him to *hit* truth occasionally in his flighty researches, or, at least, to make happy guesses in the right direction. Thus, for example, he had an idea (see M. Flourens in the *Journal des Savants*, April 1854) of the doctrine of the circulation of the blood. He attacked Galen and the Faculty with his customary violence in a treatise on Syrups (*Syruporum Universa Ratio*, Paris, 1537; Lyon, 1546). About this time, he made the acquaintance of Calvin, with whom he had several conferences or private disputations, the result of which was a public challenge; but S., after assenting to the arrangements, decamped, afraid probably, and not without reason, that his precipitate imperious way of thinking did not fit him for discussing with so cool, wary, and merciless a logician as the Genevese reformer; afraid, too, perhaps, of being unceremoniously handed over to the authorities for heresy! After living successively for some time at Lyon, Charlieu, and Avignon, and supporting himself by writing for the booksellers, he found an asylum in the palace of Pierre Paulmier, Archbishop of Vienne, in 1541, where he remained for some years, and wrote his famous *Christianismi Restitutio*, first published in 1553. The work has been twice reprinted, first by Dr Meade of London (incomplete), and again by Murr, at Nürnberg, in 1790. Its celebrity is due more to the fact, that it sealed the fate of its author, than to its intrinsic merits, the ideas being obscure, and the style incorrect. After its publication, S. wished to go to Italy, by way of Switzerland, but in passing through Geneva, was arrested and imprisoned at the instigation of Calvin (q. v.). After a long and complicated judicial procedure, S. was condemned to be burned, and the sentence was carried into execution, 27th October 1553—the hapless heretic expiring in agonies. The fate of S., after all the palliations that can be offered are weighed, remains a dark stain on the memory of Calvin (q. v.).

SE'RVIA (Turk. *Syrp*), a principality included within the limits of European Turkey, but almost independent of that power. It is bounded on the north by Austria; on the east by Wallachia and Bulgaria; on the south by Rumili and Bosnia; and on the west by Bosnia. Area 21,000 sq. m.; pop. 1,222,000. The country is mountainous and densely wooded. From the interior, numerous chains proceed northward, forming massive barriers both on the eastern and western frontiers, and sloping pretty steeply towards the swampy plains along the Save and the Danube. In the extreme north-east, near Orsova, they reach the very edge of the Danube, and along with the Eastern Carpathians on the opposite shore, imprison the great river within a wall of rock, known as the *Iron Gate* of the Danube. The highest of these chains is the Rudnik Mountains (gathered into a knotty group about the centre of the state), which in the Great Schturaz attains an elevation of 3400 feet. The *Schumadia*, or Forest, extends southwards from Belgrade for 60 miles. Beautiful landscapes are everywhere to be seen. The principal rivers (Serb. *Rjeka*) flowing through the country are the Morava and Timok, affluents of the Danube; and the Kolubara, an affluent of the Save, which itself falls into the Danube at Belgrade. The climate is temperate and salubrious, but somewhat cold in the higher regions. The soil in the valleys and level districts is fertile, and equally fitted for the rearing of cattle, the favourite occupation of the people, and the production of corn and wine; but not more than $\frac{1}{24}$th of the land is under tillage, and fully $\frac{9}{10}$ths is forest or wilderness. Oak is the most common wood, but chestnuts and fruit-trees of all sorts abound, especially pears, of which there are whole forests in some places. The mountains are believed to be rich in copper and silver, but mining is almost unknown, and manufacturing industry is in the most backward condition.

Constitution, Internal Administration, &c.—The constitution now in force dates from 1869.—The land is divided into 17 *Ocruzia*, or circles (Turk. *Kazas*); each circle has a prefect and a court of the first instance, and sends a deputy to the *Scubsch'tina*, or national parliament. The circles are subdivided into 53 *Srezi*, or arrondissements, and these again into 1152 *Obsch'tine*, or parishes, each of which has a justice of peace court. The constitution of 1869 confirms anew the hereditary title of the princes of the house of Obrenovitch, renders the 5 ministers responsible to the nation, and accords the exercise of legislative power simultaneously to the President and the 'Scubsch'tina,' which has the rights and character of an ordinary deliberative body, while the Senate has been transformed into a Council of State charged with the preparation of laws. The military force consists of about 4000 men actually under arms. The Turks keep possession of the town and fortress of Belgrade,

where they have a garrison of 15,000 men; and a few other places.

Religion, Education, and Finance.—The inhabitants nearly all belong to the Greek Church, but are independent of the Patriarch of Constantinople. Ecclesiastical affairs are managed by a Metropolitan, whose seat is at Belgrade, and by the three bishops of Uzitza, Shabatz, and Timok. For the few who acknowledge the authority of the pope and the Latin Church, there is a bishop *in part. infid.*, but who resides at Diacobar in Austrian Slavonia. S., according to recent estimates, had 298 churches, 651 parishes, and 652 priests, besides 38 cloisters. It also possessed upwards of 300 educational institutions, including several gymnasia, a Lyceum for philosophical and juristic studies, a theological college, an artillery school, a school of agriculture, and 300 elementary schools for boys, and 13 for girls! These schools are not under the control of the clergy, and education is consequently making rapid progress. In 1869 the revenue of the country was estimated at 29,596,000 tax piastres, and the expenses at 29,576,282 tax piastres.

Character.—The Servians are distinguished for the vigour of their frame, their personal valour, love of freedom, and glowing poetical spirit. Their manners and mode of life are exceedingly picturesque, and strongly prepossess a stranger in their favour. They rank among the most gifted and promising members of the Slavic family.

History.—In the earliest times of which we have record, S. was inhabited by Thracian or Illyrian races—the Bessi, Scordisci, Dardanii, and Triballi. Shortly before Christ, it was subjugated by the Romans, and under the name of *Mœsia Superior*, formed part of the province of Illyricum, whose fortunes it shared during the vicissitudes of the empire. Overrun successively by the Huns, Ostrogoths, Longobards, &c., it reverted to the Byzantine rulers about the middle of the 6th c., but was wrested from them by the Avars in the 7th c., to oppose whom the Emperor Heraclius, about 636, invoked the aid of the Serbs from Eastern Galicia. The Serbs obeyed the call, and in less than two years drove the Avars from the land, over which they themselves spread in great numbers, their settlements extending from the Morava as far west as the Dalmatian Alps and the Adriatic, and from the Save as far south as the Balkan and Lake Scutari. About the middle of the 9th c., they were converted to Christianity by missionaries sent by the Emperor Basilius, but this did not in the least abate their natural ardour for battle, and for nearly 200 years they were almost constantly at war with the neighbouring Bulgarians—the inveterate enemies of their Byzantine liege lord. In 1043, however, Stephen Bogislav expelled the imperial governors; and during 1050—1080, his son, Michael, made himself wholly independent, took the title of king of S., and procured the recognition of his royal dignity from Pope Gregory VII. For the next hundred years, the Serbs had to fight hard to maintain their independence, but the struggle terminated in their favour; and in 1165, Stephen Nemanja founded a dynasty which lasted for two centuries, during which period the kingdom of S. attained the acme of its power and prosperity. Under Stephen Dushan (1336—1356), the greatest monarch of the Nemanja dynasty, it embraced the whole of Macedonia, Albania, Thessaly, Northern Greece, and Bulgaria. The progress of the Turkish arms, however, was fatal to its welfare, and in 1389 King Lazar fell in the disastrous battle at Kossovopolje. Sultan Bajazet divided the country between Lazar's son, Stephen, and Lazar's son-in-law, Vuk Brankovitch, but compelled both to pay tribute, and to follow him in war. Gradually the Serbs sunk more and more under the Turkish yoke, until, in 1459, S. was thoroughly subjugated by the Sultan Mahmud. It was uniformly the theatre of the bloody wars between Hungary and Turkey, and frequently suffered the uttermost horrors of devastation. Prince Eugene's brilliant successes for a moment flashed a ray of hope into the miserable hearts of the long-suffering Serbs, and by the treaty of Passarowitz (1718), a considerable portion of the country was made over to Austria; but in 1739 it reverted to Turkey, and for the next 60 years the cruelty and oppressions of the Pashas and their Janizaries surpass all belief. At length the unhappy people could endure the tyranny of their foreign masters no longer, and in 1801 an insurrection broke out, headed by George Czerny (q. v.), which, by the help of Russia, ended in the triumph of the patriots, and in the election of Czerny by the people as Prince of Servia. The invasion of Russia by France, however, left the Serbs at the mercy of their late rulers, and the war again broke out. Czerny was forced to flee, and the tyranny of the Turks became more ferocious than ever. Again the people flew to arms under the leadership of Milosch Obrenovitch, and were a second time successful in winning back their liberties. Milosch was chosen Prince of Servia in 1815, and confirmed in his office by a hatti-sherif of the sultan. He ruled with indifferent success till 1839, when he was forced to abdicate; but in 1858 he was restored to his former dignity, which was made hereditary in his family. Prince Milosch died in 1860, and was succeeded by his son Prince Michael III., and by Milan IV. in 1868.

Language and Literature.—The Servian language, called also the Illyrian, belongs to one of the four great divisions of the Slavic family, and is more nearly allied to Russian than to Polish or Bohemian. It is distinguished from the other members of its division by the predominance of vowels, and consequently by its soft, melodious resonance. This character it owes in part to the influence of the Italian and Greek languages—the former influence being the result of commercial intercourse; the latter, of community of religious belief. The long domination of the Turks has also left unmistakeable traces on the Servian tongue; nevertheless, it has on the whole preserved a genuine Slavic character, possessing along with the other members of that family a complete system of declension and conjugation, along with a free syntax. The old classical modes of speech and metres are also imitated with facility in it. According to Schafarik, it is spoken (in the three dialects—Herzegovic, Razavic, and Syrmic) by more than 7,000,000 people, of whom 4,500,000 are under Austrian, 2,500,000 under Turkish, and a few under Russian authority. While their kinsmen, the Croats and Winds, use Roman characters, the Serbs proper employ the alphabet of Cyrill. Vuk Stephanovitch published a *Grammar of the Servian Language* at Vienna, in 1814, which was translated into German by Grimm (Berl. 1824); and subsequently a *Dictionary* (2d ed. Vienna, 1852). Very useful also are Berlic's *Illyrian Grammar* (Agram, 1842; Vienna, 1854); and Mazuranitz and Uzarewitz's *Dictionary* (Agram, 1842). See Schafarik's *Serb. Lese-körner oder historisch-kritische Beleuchtung der Serb. Mundart* (Pesth, 1833).

After their conversion to Christianity, the Serbs, like the Russians, employed the old Slavic church-language in writing, but in two different styles, one called the church style, and the other the chancery or legal style. The most important monument of the latter is the 'Law-book,' published by King Stephen Dushan, though the oldest extant specimens go back as far as the 11th century. The

literary remains of the former are more numerous, and embrace ecclesiastical, devotional, and historical works, for the most part composed by the clergy and the monks. With George Brankovitch (born 1645, died 1711), who wrote a *History of Servia* from the origin of the nation to his own time, this first or medieval period in Servian literature closes. The second or modern period is characterised in its commencement by an effort to raise the spoken language of the Serbs to the dignity of a written language. The consequence was, for a considerable time, the literary language of S. was a chaos of confusion, writers not appearing able to make up their minds which dialect to use, and spoiling their productions by a barbarous mixture of both; and it was not till Vuk Stephanovitch published his *Grammar of the Servian Language* (1814), and his *Songs of the Servian People*, that the victory of the reformers was complete. Since then, the spoken language of S. has also become the language of literature. These Servian popular songs or ballads constitute by far the finest part of Servian literature. The picturesque scenery of the land, and the free solitary life led in the mountain ranges, kindled the imagination of the people, and awoke the voice of song at an early period. Some of the ballads—now so widely known throughout Christendom by means of translation—go back to a period anterior to the appearance of the Turks in Europe. In a wonderful manner, they combine the rude strength, spirit, and naïveté characteristic of the ballad everywhere, with oriental fire and Greek plasticity. They are invariably unrhimed, but preserve at the same time a rhythmic measure. See Kapper's *Volkslieder der Serbien* (2 vols. Leip. 1852); and Bowring's *Servian Popular Poetry* (Lond. 1827), and Owen Meredith's *Serbske Pesme* (Lond. 1861); the last, however, a book of doubtful honesty. Among the poets who acquired distinction in the first part of the century, and have employed the vernacular, the most important is Lucyan Muschiki (died 1837), Archbishop of Carlovitz, whose *Poems* appeared at Pesth in 1838. Of recent or living Servian poets, the most gifted are Branko Raditshevitz and Jovan Ilitz. As yet, science has made little progress. In another branch of the Servian people—the so-called Illyrians, especially the Dalmatians, who profess the Roman Catholic faith—literature received an earlier and more artistic development than among the Serbs of the Greek Church. In the 12th c., a priest of Ducla (Dioclea) wrote a Chronicle, first in Slavic, and afterwards in Latin, fragments of which are still extant. During the 13th and 14th centuries, devotional works in the vernacular were numerous, and towards the end of the 15th c. the republic of Ragusa (Slav. Dubrovnik) obtained the name of the 'Illyrian Athens' on account of the brilliant success with which it cultivated literature, art, and science. Epic, lyric, and dramatic poetry, history and jurisprudence, are all admirably represented. The list of its poets is particularly large. Towards the end of the 18th c., literary activity abated among the southern or Illyrian Serbs, but at the same time began to increase in the north, especially in Croatia and Hungary.—See Ristitz, *Ueber die Serb. Literatur* (Berl. 1853), and, in English, Talvi's *Historical View of the Languages and Literature of the Slavic Nations* (New York, 1850).

SERVIA, Woiwodina of, and BANAT OF TEMES. See Austria and Banat.

SERVICE (*Pyrus domestica* [see Pyrus], the *Sorbus domestica* of many botanists), a tree of fifty or sixty feet in height, with pinnated leaves, which are downy beneath, and their leaflets serrated upwards, and small white flowers in panicles, a rare native of England, found also in various parts of Europe, the west of Asia, and the north of Africa, and cultivated for its fruit, which is obovate, and about an inch in length, resembling a small pear, but pleasant only in a doughy and over-ripened state, like the medlar. It is more cultivated in Italy, Germany, and France than in Britain. The tree is of very slow growth, and attains a great age. The timber is valuable, very heavy, fine-grained, and susceptible of a high polish, possessing a strength and durability which particularly adapt it for some purposes of the machine-maker. It is used also for making mathematical rulers, &c.—The name Wild Service is given to an allied species, *Pyrus torminalis*, also called the Sorb, a common native of the middle and south of England, and of the middle and south of Europe—a small tree, with a spotted fruit, considerably larger than that of the common hawthorn, which, like the fruit of the true service, becomes mellowed and pleasant by keeping, and is regularly brought to the market in many parts of Europe. Large quantities are brought to London from Hertfordshire. The dried fruit is used in some places as a cure for diarrhœa. The wood is highly valued. It is hard and tough, yellowish-white, with brownish-red and dark-brown streaks.

Wild Service (*Pyrus torminalis*).
a, fruit; *b*, flowers.

SERVICE AND WORK is the name usually given to an actior brought by a workman who has done work to order, or on request, or has been engaged for a specific time.

SERVICE OF HEIRS is a proceeding in the law of Scotland by which the heir of a deceased owner of land has his relationship recognised and declared, and his feudal title to the land completed.

SE'RVITUDE, a name borrowed by the law of Scotland from the Roman law, to denote that kind of right or interest which a person often has in land of which he is not the owner, as a right to cut turf, &c. Servitudes are divided into predial and personal. A predial servitude is a right constituted over one subject or tenement by the owner of another subject or tenement; while a personal servitude is constituted over a subject in favour of a person without reference to possession of property. The only kind of personal servitude is life-rent or usufruct. The predial servitudes are those usually

referred to under the head of servitude. Such a servitude being constituted in respect of the ownership of property, passes to third parties with such ownership. The tenement over which the servitude exists is called the servient tenement, and the other is called the dominant tenement. Predial servitudes are again subdivided into rural and urban, according as they affect land or houses. The usual rural servitudes are those of passage or road, pasture, feal and divot, aqueduct, thirlage, &c. Passage or road is the right which a person has to walk or drive to his house over another's land. Pasture is the right to send cattle to graze on another's lands. Feal and divot is the right to cut turfs or peats on another's land. Aqueduct is the right to have a stream of water conveyed through another's lands. Thirlage is the right to have other people's corn sent to one's mill to be ground. The urban servitudes are stillicide, light, *oneris ferendi*, &c. Stillicide is the right to have the rain from one's roof to drop on another's land or house. Light is the right to prevent another from building so as to obstruct the windows of one's house. *Oneris ferendi* is the right of the owner of the flat above to have his flat supported by the flat beneath.

SE'RVIUS TU'LLIUS. See ROME.

SE'RVUS SERVO'RUM DE'I (Lat., Servant of the Servants of God), a form of subscription adopted by the Roman pontiffs from the days of Pope Gregory the Great, by whom, according to his biographer, Paul the Deacon, it was assumed as a practical rebuke of the ambitious assumption of the title of 'Ecumenical (or universal) Patriarch,' by John, surnamed Nesteutes, or the Faster, the contemporary Patriarch of Constantinople. Gregory is said, indeed, by Paul to have been the first Christian bishop by whom this humble form was employed. This, however, is certainly a mistake, the same designation having been frequently used by bishops before the time of Gregory. Gregory was probably the first of the bishops of Rome to adopt it as a distinctive title. It is found in all the letters of Gregory which Venerable Bede has preserved in his History.

SE'SAMOID BONES are small bones met with in the substance of the tendons of muscles in the neighbourhood of certain joints. They derive their name from the Gr. *sēsamē*, a kind of Indian grain, which they were supposed to resemble. In the human subject, the patella is the best example; and beside it, they are commonly met with only on the palmar aspect of the joint which unites the metacarpal bone with the first phalanx, and in the corresponding position in the toe, there being two in each position, and their object being to increase the leverage of the short flexor muscles of the thumb and toe. They are much more abundant in the great majority of mammals than they are in man.

SE'SAMUM, a genus of plants of the natural order *Bignoniaceæ*, suborder *Pedaliaceæ*, a suborder characterised by wingless seeds, and placentæ with woody lobes attached to the inner wall of the fruit. The calyx of S. is five-parted; the corolla bell-shaped and five-parted, the lowest lobe prolonged; the stamens four, two longer than the others, and a rudimentary fifth stamen; the capsule is oblong, almost four-celled, two-valved, many-seeded. The species are natives of India and Africa, and are annual plants, covered with hairs, their flowers solitary in the axils of the leaves, on very short stalks. They are so similar as to be sometimes reckoned mere varieties of one species, *S. Indicum*. The sweet oleaginous seeds are used in some countries, as in Central Africa, for making a kind of hasty-pudding. In Egypt, they are eaten, strewed on cakes. The bland fixed oil of S. obtained from the seeds by expression, is used as an article of food, and for medicinal purposes, like olive oil. It keeps long without becoming rancid. It is much used by the women of Egypt as a cosmetic. For the sake chiefly of its oil, S. is much cultivated in India, China, Japan, and in many tropical and subtropical countries, and has been cultivated from very ancient times. It is too tender for the climate of Britain. The oil-cake, mixed with honey and preserved citron, is an oriental luxury. The leaves of S. abound in a gummy substance, which they readily impart to water, making a rich bland mucilage, which is used in the southern parts of the United States as a demulcent drink. S. is sometimes called *Tilseed*.

SESBA'NIA. See DHUNCHEE.

S'ESHA is, in Hindu Mythology, the great king of the serpent race, on which Vishn'u reclines on the primeval waters. He has a thousand heads, which also serve as a canopy to Vishn'u; and he upholds the world, which rests on one of his heads. His crest is ornamented with jewels. Coiled-up, S. is the emblem of eternity. He is often also called *Vâsuki* or *Ananta*, the eternal.

SESO'STRIS, the Greek name of a celebrated Egyptian monarch, who is supposed to have conquered all Asia and Ethiopia. His name has passed into the series of those conquerors who have almost achieved universal empire. According to the Greek legendary history, when S. mounted the throne of Egypt, he began his scheme of conquest, first dividing Egypt itself into 36 nomes, placing his brother as regent, and placing on him injunctions not to assume the diadem, or interfere with the royal harem. S. then marched at the head of a large army, and invaded Libya, Arabia, Asia, penetrating further east than Darius. Advancing through Asia Minor, he invaded Europe, and subdued Thrace and Scythia, leaving a colony at Colchis on his return. In the south, he subdued Ethiopia, and placing a fleet on the Red Sea, conquered the adjacent isles, and extended his dominions to India itself. On his return to Egypt from his northern campaigns, his brother, who had disobeyed his instructions, endeavoured to destroy him, by inviting him to a banquet at Daphnæ, and treacherously attempting to burn him and his whole family by firing the house. S. threw two of his children into the fire, and making a bridge of their burning bodies, escaped. S., in his triumphs, dragged his captives attached to the wheels of his chariot. The captives were employed on the public works, the enlargement of the Hephæsteum at Memphis (q. v.), and other temples, and in the construction of canals and mounds. Memorials of his reign, it was said, were left as steles or tablets in the conquered countries; and Herodotus saw some in Palestine, which are supposed to be the tablets of Ramesses II. (see RAMESSES), still existing in the pass of Nahr-el-Kelb, or the Lycus, and the sculptured rock at Nymphi, near Smyrna. S. is said to have grown infirm and blind after a reign of 33 years, and to have ended his days by his own hand.

Not only does the greatest confusion and difficulty about identifying this monarch exist among modern, but also in the classical authors. Herodotus places his reign long before that of Cheops of the 4th dynasty. Dicæarchus makes him rule 3712 B.C., and is followed by Aristotle and other authors. Bunsen supposes that there were more than one monarch of this name, and that one was Tosorthos, of the 3d dynasty; another, Sesortesen II., of the 12th dynasty. Lepsius conjectures that he is the

Sethos I. and Ramesses II. of the 19th dynasty. But the exploits of Sesostris seem to be a conglomeration of the conquests of the kings of the 18th and 19th dynasty, especially the Thothmes and Ramesses (q. v.), who extended the empire of Egypt far to the west and east. No one monarch of the Egyptian monarchy can represent Sesostris.—Herodotus, ii. c. 102; Diodorus, i. c. 55—57; Val. Flaccus, v. 419; Strabo, xvi.; Wilkinson, *Mann. and Cust.* i. 99—106; ii. 70; iii. 190; Lepsius, *Einleit.* s. 278; Bunsen, *Aegyptens Stelle*, book ii. 85, 86, 312—324.

SESQUIA'LTERA, one of the compound stops of the organ, composed of either five, four, three, or two ranks of open metal-pipes tuned in thirds, fifths, and octaves to the diapason.

SE'SSA, a city of Southern Italy, province of Terra di Lavoro, about 38 miles north-north-west of Naples. Pop. 5133. It has a fine cathedral, a theological seminary and colleges. There are manufactories of woollen cloth. The neighbouring soil is fertile. S. is a very ancient city; it was the capital city of the Aruncii, was afterwards colonised by the Romans in 314 A. U. C., and was very flourishing under the Roman empire. It was raised to a duchy in the middle ages.

SESSION, COURT OF. See COURT OF SESSION.

SESSIONS. See JUSTICE OF THE PEACE, QUARTER SESSIONS.

SESTE'RTIUS, a Roman coin, was the fourth part of the *Denarius* (q. v.), and thus contained at first 2½ *asses* or *libræ*. The name is an abbreviation of the Latin *semis-tertius*, which was their mode of expressing 2½; and their custom was, to derive the names of all their coins from the foundation of their money-system, the *As* (q. v.). The symbols for it were indifferently HS or IIS, the former being only a modification of the latter, which expresses two units, and S for the additional half-unit (*semis*). In the Latin classics, the phrase *sestertius-nummus*, or merely *nummus*, is frequently employed to denote this coin. When the *Denarius* (q. v.) was made to contain 16 *asses*, the relation between it and the sestertius was preserved, and the latter from that time contained 4 *asses*, though the name, which was now no longer significant, was preserved. Up till the time of Augustus, when the relation of the denarius to the *as* was changed, the sestertius was worth 2 pence ½ farthing sterling, but after this period it was reduced to 1 penny 3½ farthings sterling. The sum of 1000 sestertii was called *sestertium* (after Augustus, = £7, 16*s*. 3*d*.), which was the 'money of account' (never a 'coin') used in the reckoning of large sums of money.

SE'STRI LEVA'NTÉ, a seaport of North Italy, 26 miles east-south-east of Genoa. It is situated on a little bay near the mouth of the Gromolo, and has five foreign consulates. Its Church of the Nativity has some valuable paintings. Pop. 2136.

SE'STRI PONE'NTÉ, a town of North Italy, 4 miles west of Genoa, stands on the high road which runs along the sea-coast. There is a large government factory of tobacco. Pop. 6444.

SETA'RIA. See MILLET.

SETHE. See COAL-FISH.

SE'THITES, the name given to an obscure Gnostic sect of the 2d c., allied to the Ophites, or worshippers of the serpent; they belonged to that class of religionists who, in evolving what they regarded as their system, approached paganism. Accepting the Christian mode of thought and its terminology, they utterly disregarded the great facts of Scripture history, maintaining that Seth reappeared in the person of the Messiah, and affirming that they possessed books written by him.—See Neander's *Kirchengeschichte* (Bohn's translation, vol. ii. page 115).

SE'TON, in Surgery, is an artificially produced sinus or channel, through which some substance—e. g., a skein of cotton or silk, or a long flat piece of india-rubber or gutta-percha—is passed so as to excite suppuration, and to keep the artificially formed openings patent. (The term is, however, very often employed to designate the inserted material.) Setons are established in the subcutaneous tissue of the body (1) as counter-irritants, or (2) to act as a drain on the system at large, or (3) to excite inflammation and adhesion. For the purposes of counter-irritation, setons are usually inserted in the neighbourhood of the affected parts; but when intended to act as a drain on the system at large—e. g., in threatened head-affections—the nape of the neck is the part always selected. The operation is very simple. A longitudinal fold of skin over the spines of the cervical vertebræ is raised by the fingers from the deeper structures, and is transfixed by the seton-needle rather obliquely, so that one of the openings shall be rather more dependent than the other. The needle must pass somewhat deeply through the subcutaneous tissue, as, if it passed immediately beneath the skin, the latter would probably slough over the whole track of the wound. The inserted material should be smeared with oil, and may be allowed to remain undisturbed for four or five days, till there is a free discharge of matter, after which a fresh portion should be drawn daily through the wound.

For the purpose of exciting local inflammation and adhesion (which is a result of the inflammation), setons are employed in the treatment of hydrocele, enlarged bursæ, ranula, bronchocele, ununited fractures, &c. In the two last-named cases, their use is, however, not unattended by danger.

The word *seton* is derived from the Latin *seta*, a hair, because hairs were originally employed as the inserted material. Indeed, at the present day, it is the custom of many of the nomadic tribes of Central Asia to insert a hair into the heels of their prisoners, which lames them to such an extent as to prevent their escape.

SETT, in Scotch Law, was used to denote the constitution of a burgh, whether founded on immemorial usage or modelled by the Convention of Burghs (q. v.).

SE'TTÉ COMMU'NI DI VICE'NZA, a district consisting of seven communes or parishes in the neighbourhood of Vicenza, the language and population of which are plainly Teutonic, and have maintained themselves pure and unmixed in the midst of a Latin people from the days of the Roman republic. The inhabitants are believed by antiquaries to be descendants of the remnant of the Cimbrian army which was defeated with great slaughter by Marius, and is supposed to have escaped to the mountains, and there fixed a permanent settlement. Their language is perfectly intelligible to any German scholar. Specimens of this dialect, and of a similarly isolated Teutonic dialect which is found near Verona, are given by Adelung in the *Mithridates*, ii. p. 215.

SETTER, a kind of dog which derives its name from its habit of *setting* or crouching when it perceives the scent of game, instead of standing, like the pointer. Setters, however, are now trained to adopt the pointer's mode of standing whilst marking game. The S. was originally used to assist in the capture of game by the net. It is supposed to derive its origin from a mixture of the pointer and the spaniel. It is larger than the spaniel; its hair is less smooth than that of the pointer, and has more

of the waved character of that of the spaniel, to which there is a resemblance also in the ears. The tail is bushy. There are several breeds of the setter. The general colour of the *English S.* is a white ground, with large spots or blotches of liver-colour or red. The *Irish S.* has larger legs in proportion to the size of the body. The *Russian S.* is

English Setter.

covered with woolly fur, much matted together. Each of these breeds has its peculiar merits. All setters have the soles of the feet well covered with hair, so that they can bear hard work on rough ground. They soon become exhausted, however, unless they have access to water. The S. is much employed by sportsmen. It is one of the most affectionate, gentle, and intelligent of dogs.

SETTLE, Elkanah, was born at Dunstable, in the year 1648. He completed his education at Trinity College, Oxford, which he left without taking a degree, and repaired to London, to seek his subsistence by literature. In 1671, he made something of a hit by the production of his tragedy of *Cambyses;* and the Earl of Rochester and others, wishing to annoy and insult the great Dryden, loudly hailed in him the superior genius of the two. Through the influence of Rochester, to his next tragedy, *The Empress of Morocco*, the unwonted honour was accorded of being played at Whitehall by the lords and ladies of the court, and in this way a great run was secured for it when it came before the general public. In the insolence of success, the author printed along with it a Preface, in which Dryden was severely assailed. Solely in virtue of the quarrel thus engendered is S. now remembered. In his great satire, *Absalom and Achitophel*, Dryden scourged him with his scorn, so that in some sort he survives for us, if only as a shrieking ghost. Having no real strength of talent, he speedily relapsed into obscurity. The post of poet-laureate for the city he had obtained, and he continued to retain. By writing in this capacity verses for city pageants and festivities, and producing pieces to be acted in the booths of Bartholomew Fair, the some-time rival of Dryden was fain to eke out a wretched subsistence. In his destitute age, he was admitted to the Charter-house, where in 1723 he died, his works having predeceased him.

SETTLED ESTATE, in English Law, means an estate held by some tenant for life, under conditions more or less strict, defined by the deed.

SETTLEMENT, in English Law, is used in two senses. In one case, it means the mode of securing property on married parties, so as to regulate the succession in the event of the death of either, or it may regulate the succession of parties not married. In poor-law matters, it means that kind of right which a pauper has to support by the parish by reason of his being born there, or of his renting a tenement or acquiring estate, &c. It often happens that a person becomes chargeable, that is, is entitled to be relieved by a parish in which he has no settlement, and the relieving parish can forthwith remove him to his parish of settlement. See Removal of Paupers.—In Scotland, settlement, besides the above meanings, also means the general will or disposition by which one regulates the disposition of his property after death.

SETU'BAL (frequently and erroneously called by the English St Ube's) is an important seaport city of Portugal, in the province of Estremadura, 20 miles south-east of Lisbon. It stands on the north side of the Bay of Setubal, which forms a magnificent harbour, though the entrance to it is obstructed by sandbanks. The harbour is furnished with a light-house and with broad and handsome quays, and is protected by five forts; but the valley in which the town itself stands is completely commanded by the heights in the vicinity. The town owes its importance chiefly to its trade in wine and in sea-salt, but fishing is also carried on with considerable activity. In 1862, 346 vessels, laden with 64,221 tons of salt, valued at £55,630, 15*s.*, sailed from the port; of these vessels, 24, of 3629 tons, were British. S. is the old Roman *Cetobriga*. Pop. 13,134.

SEVEN: frequently used as a mystical and symbolical number in the Bible, as well as among the principal nations of antiquity (the Persians, Indians, Egyptians, Greeks, Romans, &c.). The reason for the preference of this number for sacred use has been found in its consisting of *three*—the number of the sides of a triangle—and *four*—the sides of a square, these being the simplest rectilineal figures:—or in other equally vague circumstances. The real reason, however, seems to be astronomical, or rather astrological, viz., the observation of the seven planets and the phases of the moon—changing every seventh day. (See Week.) As instances of the use of this number in the Old Testament, we find the Creation completed in seven days, wherefore the seventh day was kept sacred; every seventh year was Sabbatical, and the seven times seventh year ushered in the Jobel-year. The three *Regalim*, or pilgrim festivals (Passah, Festival of Weeks, and Tabernacles), lasted seven days; and between the first and second of these Feasts were counted seven weeks. The first day of the seventh month was a 'Holy Convocation.' The Levitical purifications lasted seven days, and the same space of time was allotted to the celebration of weddings and the mourning for the dead. In innumerable instances in the Old Testament and later Jewish writings, the number is used as a kind of round number. In the New Testament we have the churches, candlesticks, stars, trumpets, spirits, all to the number of seven; and the seven horns, and seven eyes of the Lamb. The same number appears again either divided into half ($3\frac{1}{2}$ years, Rev. xiii. 5, xi. 3, xii. 6, &c.), or multiplied by ten—seventy Israelites go to Egypt, the exile lasts seventy years, there are seventy elders, and at a later period there are supposed to be seventy languages and seventy nations upon earth. To go back to the earlier documents, we find in a similar way the dove sent out the second time seven days after her first mission, Pharoah's dream shews him twice seven kine, twice seven ears of corn, &c. Among the Greeks the seven was sacred to Apollo and to Dionysos, who, according to Orphic legends, was torn into seven pieces; and it was particularly sacred in Eubœa, where the number was found to pervade, as it were, almost every sacred, private, or domestic relation. On the many ancient speculations which connected the number seven with the

human body and the phases of its gradual development and formation, its critical periods of sicknesses—partly still extant as superstitious notions—we cannot here dwell. The Pythagoreans made much of this number, giving it the name of Athene, Hermes, Hephaistos, Heracles, the Virgin unbegotten and unbegetting (i. e., not to be obtained by multiplication), Dionysos, Rex, &c. The 'seven sacraments,' the 'seven Free Arts,' the 'seven wise men,' and many more instances, prove the importance attached to this number in the eyes not only of ancient but even of our own times. That it played an immense part in the superstitions of the middle ages need hardly be added.

SEVEN DOLOURS OF THE BLESSED VIRGIN MARY, Feast of, a modern festival of the Roman Catholic Church, which, although bearing the name of devotion to the Virgin Mary, in reality regards those incidents in the life and passion of Christ with which his mother is most closely associated. This festival is celebrated on the Friday preceding Palm Sunday (q. v.). The 'dolours' or sorrows of the Blessed Virgin have long been a favourite theme of Roman Catholic devotion, of which the pathetic *Stabat Mater Dolorosa* is the best known and most popular expression; and the festival of the Seven Dolours is intended to individualise the incidents of her sorrows, and to present them for meditation. The seven incidents referred to under the title of 'dolours' are: 1. The prediction of Simeon (Luke ii. 34); 2. The flight into Egypt; 3. The loss of Jesus in Jerusalem; 4. The sight of Jesus bearing his cross towards Calvary; 5. The sight of Jesus upon the cross; 6. The piercing of his side with the lance; 7. His burial. This festival was instituted by Pope Benedict XIII. in 1725.

SEVEN SLEEPERS, the heroes of a celebrated legend, which is first related by Gregory of Tours in the close of the 6th c. (*De Gloria Martyrum*, c. 95), but the date of which is assigned to the 3d c., and to the persecution of the Christians under Decius. According to the narrative, during the flight of the Christians from the persecution, seven Christians of Ephesus took refuge in a cave near the city, where they were discovered by their pursuers, who walled up the entrance, in order to starve them to death. A miracle, however, was interposed on their behalf: they fell into a preternatural sleep, in which they lay for nearly 200 years. The concealment is supposed to have taken place in 250 or 251; and it was not till the reign of Theodosius, 447, that they were reanimated. On awaking, they imagined that their sleep had been but of a single night; and on one of the party (supposing the persecution still in progress) going into the city to purchase provisions privately, he was amazed to find erected in triumph on the churches and other buildings, a cross, which, as it seemed, but a few hours before, he had seen the object of contempt and blasphemy. When their wonderful history became known, they were conducted in triumphant procession into the city of Ephesus; but they all died at the same moment, as if by one common and mysterious destiny. The same legend reappears with variations at later periods of Christian history.

SEVENTH-DAY BAPTISTS. See Sabbath.

SEVEN WISE MASTERS is the title of a medieval collection of novels, important both from its contents and its wide-spread popularity. The idea of the work is as follows: A certain prince's son, instructed in all kinds of wisdom by seven sages, finds, from an examination of the stars, on his return to his father's court, that he is in danger of losing his life, if he speaks a word within seven days. His stepmother, whose allurements he had repelled, endeavoured in revenge to persuade his father to put him to death, and each day related an artfully constructed story, with the view of furthering her wicked purpose, but its effect was daily neutralised by a rival narrative told by each of the sages. At last, on the expiry of the seven days, the prince himself was enabled to disclose the base designs of his stepmother.—The work is undoubtedly of oriental origin, yet neither the period when it was composed, nor how far it spread through the East, can be ascertained with sufficient accuracy. According to Masudi, it existed in Arabic as a translation from Indian sources before the 10th c., but none of the extant Arabic versions go back so far. Nearest to the original form appears to stand the *Eight Nights* of Nakhschebi, a Persian adaptation of the Indian *Tutiname* (Brockhaus, Leip. 1845). It passed into the literature of Western Europe in the 11th or 12th c., through the medium of two redactions, a Hebrew and a Greek, the latter by Andreopulos, under the title of *Syntipas* (see *Das Buch von den sieben weisen Meistern*, translated from the Hebrew and Greek by H. Sengelmann, Halle, 1842; *Syntipas* being republished by Boissonade, Paris, 1828). The work was disseminated through Christendom; sometimes in a complete form; sometimes only particular novels were reproduced, under all sorts of names, and with all sorts of modifications; sometimes in verse, sometimes in prose. Latin versions began to appear about the beginning of the 13th c., and Keller has published a French metrical one, from a MS. of 1284 (*Li Romans des Sept Sages*, Tüb. 1836), and Henry Weber an English metrical one (third vol. of the *Metrical Romances*, Edin. 1810). There are several German versions, dating from the 14th century. In the 15th c., a popular German chapbook, *Von den sieben weisen Meistern*, was frequently reprinted (the first edition is dated Augsb. 1473), and is included by Simrock in his collection of German *Volksbücher*.

SEVEN WISE MEN, the collective designation of a number of Greek sages, who lived about 620—548 B. C., and devoted themselves to the cultivation of practical wisdom. Their moral and social experience was embodied in brief aphorisms, sometimes expressed in verse, sometimes in prose. The names of the Seven, as usually given, are Solon (q. v.), Thales (q. v.), Pittacus (q. v.), Bias (q. v.), Chilon, Cleobulus, and Periander of Corinth; but there is not absolute unanimity among the ancients either as regards the names, the number, the history, or the sayings of these famous sages. The fragments of wisdom attributed to them which have come down to us are to be found in Orelli's *Opuscula Græcorum Veterum, Sententiosa et Moralia* (Leip. 1819), and have been translated into German by Dilthey in his *Fragmente der sieben Weisen* (Darmstadt, 1835).

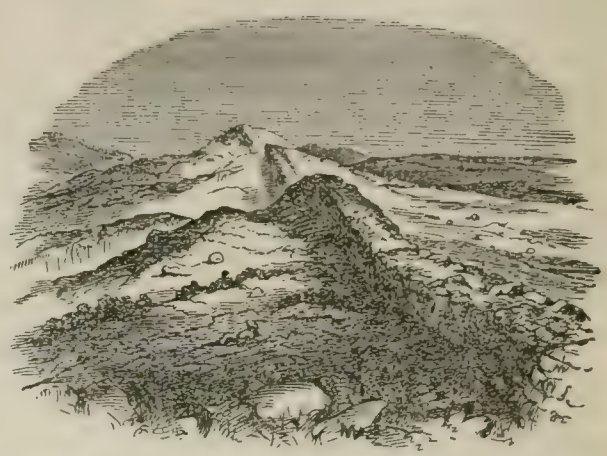
SEVEN WONDERS OF THE WORLD were, in ancient times, reckoned to be the Pyramids of Egypt, the Hanging Gardens of Semiramis at Babylon, the Temple of Diana at Ephesus, the Statue of Jupiter at Athens by Phidias, the Mausoleum (q. v.), the Colossus (q. v.) at Rhodes, and the Pharos of Alexandria. This cycle of seven wonders originated among the Greeks after the time of Alexander the Great, and they were described in a special work by Philo of Byzantium, which has been edited by Orelli.

SEVEN YEARS' WAR, The, was the third, last, and by far the longest (1756—1763) and most terrible of the contests for the possession of Silesia (q. v.). During the two former wars, the Empress Maria Theresa had plenty of other work on hand in

maintaining her claims to the Austrian dominions (see SUCCESSION, WAR OF AUSTRIAN) to offer any very effective resistance to the aggression of Frederick the Great of Prussia; but after emerging triumphantly from this contest, she took advantage of the circumstance that the king of Prussia was on bad terms with all the chief continental powers except Turkey and Spain, to renew the struggle for Silesia, which had been snatched from her at the moment of her greatest straits. She found the Czarina Elizabeth, the King of Poland and Elector of Saxony, and Louis XV. of France (or rather Madame de Pompadour), ready to enter into an offensive and defensive treaty with her. On the other hand, Britain (then at war with France) engaged to assist Prussia with an army in Hanover, and with subsidies when necessary. Resolving to anticipate his enemies, and secure a safe basis for future operations, Frederick made a sudden advance (August 1756) on Dresden with 60,000 men, took possession of the country, which he governed from this time with slight intervals to the end of the war, and cooped up the Saxon army, 18,000 strong, between Pirna and Königstein. On the Austrians under Browne advancing to relieve their allies, they were met by Frederick at Lobositz (October 1), and after an indecisive contest, were obliged to retreat. The Saxons then surrendered (October 14), and were mostly incorporated with the Prussian army, which went into winter-quarters in Saxony and Silesia. —The *second campaign* (1757) began under more favourable auspices for the Austrian coalition, as the rapid action of Frederick had taken it somewhat by surprise in the preceding autumn; besides, Sweden (subsidised by France) became a fourth in the coalition, in order to recover Pomerania, and the German Reich or Empire raised an army, 33,000 strong, to assist Austria. A combined attack was now made by a French army (100,000) on Hanover; another French army (30,000) on Hesse-Cassel (an ally of Prussia), with a view to reach Saxony; an Austrian army from Bohemia on Saxony and another on Silesia, both of them at first united under Marshal Daun, but latterly (1760) separated, under Daun and Loudon; the Russians (100,000) on the east and north-east; and the Swedes (22,000) in Pomerania; while the imperial army sometimes joined the southern French, and sometimes the west Austrian armies. To oppose these armies, numbering in all 430,000, Frederick had the combined British-Hanoverian-Hessian army (60,000) in Hanover, and a Prussian army of 200,000 strong, which was distributed, as need required, over the various points attacked; but he relied much on the rapidity of his movements, and the harmonious completeness of his plans. In April, Frederick, leaving a corps of 24,000 under Lewald to resist the Swedes and Russians, invaded Bohemia, drove in the advanced corps of the Austrians upon their main army, which he then completely routed at Prague (May 6), with a loss on his side of 18,000, and of 19,000 on the part of the Austrians. Marshals Schwerin (Prussian) and Browne (Austrian) fell in this conflict. Frederick immediately invested Prague, to which Prince Charles of Lorraine, with 46,000 men, had retreated; but Daun, who advanced from Moravia to its relief, inflicted on the Prussians a crushing defeat at Kolin (June 18), and forced them to retire from Bohemia. The north French army had meanwhile, under Marshal d'Estrees, advanced into Hanover, defeated the incapable Duke of Cumberland at Hastenbeck (July 26), and compelled him to capitulate, on condition that the whole of his army, excepting the Hanoverians, should be disbanded. But the British government refused to ratify this shameful treaty, and speedily raised another army of similar composition, which was placed under the command of Duke Ferdinand of Brunswick, an able leader, who again drove back the French, and proved himself so capable to hold them in check, that Frederick ceased to have any apprehensions from this quarter. The south French army under Soubise had also advanced in conjunction with the Imperialists under the Prince of Hildburghausen in the direction of Saxony, but Frederick was not prepared to lose this valuable vantage-ground, and falling upon them at Rossbach (q. v.) (November 5), he put them completely to rout. During his absence, however, the Austrians had broken into Silesia, routed his armies, and compelled them to retire; so, compelled to use the utmost expedition in returning, he collected a small army, defeated a thrice as numerous force of Austrians under Prince Charles of Lorraine at Leuthen (December 5), and recovered Silesia. On the east, the Russians had appeared in great force, captured Memel, committing the most horrible devastations, and had routed Lewald at Grossjägerndorf (August 30), when the change of Russian policy due to the illness and apparently impending demise of the czarina, caused them to relinquish almost all their conquests; Lewald then attacked and defeated the Swedes, driving them under the walls of Stralsund. Thus closed the second campaign, leaving matters very much as they were at the commencement.—Duke Ferdinand opened the *third campaign* (1758) by driving the French from Lower Saxony, pursued them across the Rhine, and defeated them near Krefeld (June 23); but Contades, the new French commander, having obtained the co-operation of Soubise, compelled him to retrace his steps, till, receiving a reinforcement of 12,000 British, Ferdinand again advanced, throwing Contades between the Rhine and Meuse, and Soubise between the Rhine and Main. Meanwhile, Frederick had not been idle, for after being driven out of Moravia (which he had invaded in spring) by Daun, he marched northwards with a portion of his army to meet the Russians, who, the czarina having recovered, had again invaded Brandenburg, and defeated them in a desperate battle at Zorndorf (August 25), compelling them to retreat into Poland. Frederick's presence was next needed in Saxony, where his brother, Prince Henry, was being hard pressed by Daun with superior forces; but on his arrival the Austrians retreated eastward till October 14, when Daun turned, took Frederick completely by surprise, and gave him a severe defeat at Hochkirch (q. v.), though before the end of the year the Prussians were again in possession of Saxony. Thus passed another campaign with a slight advantage to the Prussians.—The *fourth campaign* (1759) (preceded by fruitless attempts at negotiation with France, on the part of Frederick), though signalised by only two great actions, was more unfortunate for Prussia. The French under Soubise had captured Frankfurt during the winter, and the Duke of Brunswick, in attempting to recover it, was defeated at Bergen (April 13), by Broglie (the successor of Soubise), and compelled to resign the whole of Hesse to the French; but later in the year, his signal victory at Minden (August 1) over Contades and Broglie, and that of his relative, the hereditary Prince of Brunswick, at Gohfeld on the same day, recovered most of Westphalia, and drove the southern French beyond the Lahn and Rhine. But in the Saxon district, although Prince Henry invaded Bohemia (April), capturing immense supplies, and cleared Franconia (May) of Austrians and Imperialists, he subsequently evacuated Saxony, which was then occupied by the Imperialists, and Loudon's Austrians advanced into Lusatia. In Silesia, Fouqué gallantly

kept the Austrians at bay; and Dohna continued to coop up the Swedes about Stralsund, keeping at the same time an eye on the Russians; but the latter soon gathered in such force that he was compelled to retreat. His successor, Wedel, in attempting to bar their advance, was routed near Züllichau (July 23), and though Frederick hastened to his assistance, attacked them at Kunersdorf (q. v.) (August 12), and had almost gained the day, the arrival of Marshal Loudon with an Austrian force turned the tide, and converted this almost victory into the most signal defeat suffered by the Prussians during the whole war. On the following morning, he could hardly muster 5000 men, but, luckily, the Russians shewed no inclination to follow up their victory, and by untiring perseverance, the Prussian monarch succeeded in raising another army 28,000 strong. Though it seemed almost impossible for him to prevent the meditated junction of the Russians and Austrians in Brandenburg; yet, by dint of skilful manœuvring, he succeeded in compelling the Russians to retire to Poland; and Prince Henry, by cutting off their supplies, forced the Austrians into Saxony. On November 21, however, he suffered a severe blow in the capture of Finck with 11,000 Prussians, at Maxen in Saxony. With greatly diminished strength, an exhausted treasury (chiefly supplied by the English subsidy, the taxes of Saxony, and forced contributions on Mecklenburg, Saxony, and Anhalt), a desolated territory incapable of affording either men or supplies, and gloomy forebodings of the final issue, though with unfaltering resolution never to yield, Frederick prepared for his *fifth campaign* (1760).—His army in Prussia, now reduced to 90,000 men, mostly foreigners and raw recruits, was still further diminished by the capture of Fouqué with 8000 men in Silesia, followed by Marshal Loudon's conquest of that province, though the brilliant victory of Liegnitz (August 15) subsequently restored him the north-western division of it; he then joined his brother, Prince Henry, drove the Russians across the Oder, and Daun into Bohemia; but his strength was now becoming glaringly insufficient for the task to which he had set himself; the Russians and Austrians captured and plundered Berlin (October 3); the Swedes came down from the north, and Loudon's Austrians upwards through Silesia, so that he was now fairly in the toils. But, like a lion in the midst of the hunters, he turned upon his most able and pertinacious adversary, Daun, terribly routed him at Torgau (November 3), in Saxony, then drove Loudon into Glatz, and frightened away the Russians to Poland, and the Swedes to Stralsund. In the west, the fortune of Prussia was in the ascendant, and the French, defeated by Prince Charles of Brunswick at Einsdorf (July 13), and by Duke Ferdinand at Marburg (July 31), were again confined to Hesse.—The *sixth campaign* (1761) on the Rhine commenced still more auspiciously for Frederick, as the French were driven in detail from their strongholds, had their supplies captured, suffered defeat by the Hanoverians at Langensalza (February 14), and by Duke Ferdinand at Villingshausen (July 15), though in the end Broglie and Soubise again gained possession of Hesse. In Silesia, Frederick attempted to bar the progress of the Austrians, so as to prevent their junction with the Russians, and so opposing 130,000 men to his poor remnant of 50,000; but in vain; however, the union was productive of no ill results to him, for scarcity of provisions speedily compelled the Russians to retreat to Poland, after which Loudon retired to Upper Silesia, capturing Schweidnitz with 3700 men on his way. In Saxony, Prince Henry had to retreat before Daun, and the Prussians were ejected from Pomerania by the Russians and Swedes, all subsidies from Britain stopped by the Earl of Bute after George II.'s death, and the country ravaged in all directions, so that things were now in a desperate condition, and Prussia almost at its last gasp. Frederick's assailants had cooped him up within Southern Brandenburg and North-western Silesia, and though as resolute as ever to fight on, it seemed as if another campaign must bring him to final ruin. But the death of the czarina (January 5, 1762) converted the most powerful of his enemies into a fast friend; Sweden, which had suffered uninterrupted reverses during the whole war, also retired from the alliance—and the *seventh campaign* (1762) commenced on equal terms, as Austria and France were almost as much exhausted as Prussia. On the refusal of Austria to submit her cause to arbitration, the Czar Peter III. joined his army to that of Frederick; but his successor, Catharine II., ordered the return of the army, though her strict neutrality was of itself an immense benefit. Frederick had now no fears for the result. Nor had he any reason, as subsequent events shewed, for on July 21 he drove an Austrian force from its intrenchments at Burkersdorf, and following up his success, routed Daun at Reichenbach (August 16), and took Schweidnitz (October 9); while Prince Henry, by a series of fortunate manœuvres, possessed himself of the passes of the Erzgebirge, and with the valuable aid of Seidlitz, completely overthrew the other Austrian army at Freiberg (October 22); and the two Brunswicks nobly sustained the glory of Prussia at Wilhelmsthal (June 24) and Luternberg (July 23), capturing Cassel, and recovering the whole of Hesse. France now gave up a contest from which she had gathered nothing but military disgrace, and concluded treaties with Britain and Prussia; while Prussia and Austria agreed to an armistice with regard to Saxony and Silesia, of which the astute Frederick took advantage to send Kleist on a raid through Franconia and Bavaria, which had the effect of withdrawing the minor German states from the coalition. Maria Theresa was now left alone, and sorely against her will, was compelled to conclude the peace of Hubertsburg, 15th February 1763, which finally acknowledged Frederick as the lord of Silesia. This long and desperate conflict made no change in the territorial distribution of Europe, but it increased tenfold the moral power of Prussia, and gave its army a prestige which it retained till the battle of Jena. It cost Europe a million lives, and prostrated the strength of almost all the powers who had engaged in it.—See for a complete account, Carlyle's *History of Frederick the Great*.

SE'VERALLY, in English Law, is the enjoyment by an individual of an estate, in contradistinction to Joint (q. v.).



SE'VERN, one of the most important and beautiful, and after the Thames, the largest of the rivers of England, rises from a chalybeate spring on the eastern side of Plinlimmon, about 11 miles west of Llanidloes, in Montgomeryshire, North Wales. Flowing eastward from its source to Llanidloes, to which town it retains its original British name of Hafren, it afterwards flows north-east to the eastern boundary of Montgomeryshire, then east-south-east, past Bridgenorth in Salop, and finally southward through Worcester and Gloucester, in which last it begins to form its estuary. It is navigable for barges to Welshpool in Montgomeryshire, 180 miles from its mouth. Its entire length is 210 miles, and it drains an area of more than 6000 sq. miles. The chief affluents of the S. are the Terne, and the Upper and Lower Avon on the east, and the Teme

and Wye on the west. A canal 18½ miles long, and navigable for vessels of 350 tons, extends from Gloucester to the upper portion of the estuary of the river, and thus materially shortens the navigation of its lower course. The Montgomery Canal extends from Welshpool to Newton, and other canals establish communication between the S. and the Thames, Trent, Mersey, and the other important rivers of the middle districts of England. The *bore*, or tidal wave, which rushes up the S. with a velocity at times of 14 miles an hour, raises the water 9 feet in height at Gloucester, below which embankments have been constructed along the water-course to prevent inundation. See BRISTOL CHANNEL.

SEVERUS, ALEXANDER. See ALEXANDER SEVERUS.

SEVERUS, L. SEPTIMIUS, Roman emperor, was born 11th April 146 A.D., near Leptis Magna, on the north coast of Africa, of a family of equestrian rank; and after receiving an excellent education, removed to Rome, where he became prætor, 178 A.D. He was subsequently commander of a legion in Gaul, and governor of Gallia Lugdunensis, Pannonia, and other provinces. After the murder of Pertinax, he was proclaimed emperor, 193 A.D., at Carnutum, and promptly marched upon Rome, where the puppet Julianus had by purchase obtained the imperial purple. His arrival before Rome was the death-signal for Julianus; and after taking vengeance on the murderers of Pertinax, converting his most formidable rival, Clodius Albinus, into an ally by creating him Cæsar, and distributing an extravagant largess to his soldiers, he marched against Pescennius Niger, and conquered him at Issus, 195 A.D. A glorious campaign in the East, and a three years' siege, followed by the capture of Byzantium, were followed by a desperate struggle with his jealous rival, Clodius Albinus, whom, after an obstinate conflict at Lyon, in which 150,000 were engaged on each side, he conquered, 197 A.D. The usual games to the degenerate citizens of Rome, and largesses to the troops, followed, after which S. returned to Asia, accompanied by his sons Caracalla and Geta, met with the most brilliant success in the campaign of 198 A.D. against the Parthians, and took and plundered their capital, Ctesiphon. After a war with the Arabs, in which S.'s usual good-fortune deserted him, and a general visit to his various eastern dominions, he returned to Rome, 202 A.D., and gratified the popular taste by the exhibition of shows of unparalleled magnificence, also distributing another extravagant largess to the citizens and prætorians. A rebellion in Britain drew him to that country in 208 A.D.; and at the head of an immense army, he marched, it is said, to the extreme north of the island, encountering enormous hardships, to which no less than 50,000 of his soldiers succumbed, and securing no permanent advantages. To secure to some extent the natives of South Britain from the incursions of the Meatæ and Caledonians, S. commenced the wall which bears his name, and died soon after at York, 4th February 211 A.D. S. was an able, vigorous, and just ruler, and a skilful warrior, but totally devoid of high moral sentiment, a deficiency especially observable in cases where his own interests were involved.

SEVERUS, WALL OF, a rampart of stone built by the Roman Emperor Severus in Britain, 208 A.D., between the Tyne and the Solway. On the first subjugation of Britain by the Romans, a line of forts had been constructed by Agricola, extending from the Forth at Edinburgh to the Clyde at Dumbarton. The Emperor Hadrian, on visiting Britain, 120 A.D., threw up for the protection of the Roman province a wall of turf extending across the narrowest part of the island, between Tyne and Solway. Twenty years later, Antoninus Pius, whose lieutenant, Lollius Urbicus, had gained fresh advantages over the northern tribes, endeavoured to check the inroads of the Caledonians by erecting another rampart of earth between the Forth and Clyde, connecting Agricola's line of forts. But after a vain struggle of 60 years, the Romans found it necessary to abandon the whole district between the walls, and Septimius Severus built a rampart of stone

A Portion of the Wall of Severus, near Housestead, Northumberland.

immediately to the north of the wall of Hadrian. Towards the close of the 4th c., Theodosius, for a brief period, reasserted the Roman dominion over the district between the walls of Antonine and Severus, which, in honour of the Emperor Valens, obtained the name of Valentia. But this newly-established province was soon lost, and it was not long before the Romans finally abandoned Britain. Many remains of the Roman walls are yet to be traced.

SÉVIGNÉ, MADAME DE, MARIE DE RABUTIN-CHANTAL, was born at Paris, 6th February 1626. She was the only daughter of the Baron de Chantal, Celse-Benigne de Rabutin, and his wife, Marie de Coulange. She was left early an orphan; and at the age of six the care of her education devolved on her maternal uncle, the Abbé de Coulange, an excellent and amiable man, who most conscientiously acquitted himself of his charge, and for whom through life his niece entertained the tenderest affection. She was carefully instructed in all the knowledge which then appertained to the education of a French gentlewoman; by the eminent scholar Menage she was taught Latin, Italian, and Spanish; and M. Chapelain, another literary notability of the time, also assisted in her culture. At the age of 18 (Aug. 1, 1644), she was married to the Marquis Henri de Sevigné, the representative of an ancient House in Brittany. The union was not a happy one. The marquis was 'a man of wit and pleasure,' of the type of the period; his wit he exhibited by his happy way of squandering his wife's fortune, and he took his pleasure in neglect of her, and addiction to other women. After a time, he was killed in a duel (5th February 1651), by a certain Chevalier d'Albret, his rival in a love-affair. Left with a son and daughter, S. now for a few years retired almost wholly from society, and devoted herself to their education. In 1654, she returned to Paris, where her beauty, her wit, her happy social tact and vivacity, concurred, with the charm of her sweet and kindly nature, to insure her unrivalled success in the brilliant society of the period. Her lovers were legion, and among them were numbered some

of the most distinguished men of whom France could then boast, as the Prince de Conti, Turenne, Fouquet the Superintendent of Finance, and others. But they sighed in vain: all offers of marriage she steadily declined; and from any of those lighter ties, there and then most leniently looked on—if not almost considered *comme il faut*—she has left no spot upon her reputation. For her virtue she must have credit as virtue, and not merely the coldness which simulates it; for she was obviously of a warm, eager, even somewhat impulsive nature. Her numerous and warm friendships, with her absolute devotion to her children, may have sufficed as food of a heart not unlikely, in lack of these, to have craved a more perilous diet. Her affection for her daughter in particular, who in 1669 became Madame de Grignan, was the ruling passion of her life; and to the separation of the mother, over long periods, from 'this infinitely dear child,' the world is indebted for by much the larger moiety of the collection of Letters which has given fame in perpetuity to Madame de Sévigné. Madame de Grignan was one of the most beautiful and accomplished women of her time, and every way worthy of the love thus lavished without stint upon her. If she did not reciprocate its full fervour, *that*, as the shrewd mother well knew, was simply in the nature of the case; and not to have demonstrated in return more rapture than she really felt, ought to count as a point in her favour, rather than reverse-wise as it has been held to do. If it was the one main grief of Madame de S. to be forced to live apart from her daughter, the happiness of dying beside her, may perhaps have a little consoled her for it. In 1696, while on a visit to the Château de Grignan, she was seized with malignant small-pox, and died at the age of 70.

The Letters of Madame de S., on which her fame securely rests, are charming in the *abandon* and easy *naïve* frankness with which they reveal her beautiful nature. They sparkle with French *esprit*, and spontaneous gaiety of heart; and their writer is scarce anywhere quite equalled in the delicate *finesse* with which, in a few careless rapid words, she flings off a scrap of light narrative, dashes in a little graceful picture, or points a dramatic situation. Above all remarkable is the lightly-moved and ever-active sympathy which keeps her exquisitely *en rapport* with the interest of whatever may be passing before her.

SE'VILLE (Span. *Sevilla*, the *Hispalis* of the Romans), a famous city of Spain, formerly capital of the ancient kingdom, and now of the modern province of the same name, stands on the left bank of the Guadalquivir, 94 miles by railway north-north-east of Cadiz. The city is almost circular in shape, is surrounded by Moorish walls, surmounted with 66 (formerly 166) towers, and pierced with 15 gates, and is 5 miles, or, including its 10 suburbs, 10 miles in circumference. Held by the Moors for five centuries, and entirely rebuilt by them from the materials of former Roman edifices, S. was long a purely Moorish city, and the old Moorish houses, which age, in this dry climate, has done little to destroy, are still the best houses to be seen. Half of the city still preserves its ancient character; but changes are taking place every year. The narrow tortuous streets that kept out the sun, with their wide spacious mansions, with ample courts and gardens, so perfectly suited to the climate, are giving way to spacious straight streets of small, hot houses, open to the blaze of noon. The cathedral, one of the largest and finest in Spain, is an imposing edifice, of which the solemn and grandiose are the distinctive qualities. It was completed in 1519, is 431 feet long, 315 feet wide, has 7 aisles, and an organ with 5400 pipes. The pavement is in black and white checkered marble. The cathedral is superbly decorated. Its painted windows are among the finest in Spain, and it contains paintings by Murillo, Vargas, the Herreras, &c. Attached to the cathedral is one of the most remarkable towers in the world. It is called the Giralda (i. e., a weather-cock in the form of a statue), and is in all 350 feet high. This Moorish tower was built in 1196, and was originally only 250 feet high, the additional 100 feet being the rich filigree belfry added in 1568. The pinnacle is crowned by a female figure in bronze, 14 feet high, and 2800 lbs. in weight, and which veers about with the slightest breeze. From this great tower the *Mueddin* (q. v.) of Mohammedan days called the faithful to prayers. The royal residence, the Alcazar (*Al-Kasr*, house of Cæsar), contains several noble halls, and much delicate ornamentation, that rivals that of the Alhambra. The house in which Murillo lived and died is still to be seen here. The finest pictures in S. are to be seen in the cathedral, the Caridad, the Museo, and the University. S. contains 74 churches; but prior to the suppression of monasteries, it contained 140. Besides the university (of four faculties), there are many educational institutions. The city contains upwards of 100 squares. The Fabrica de Tabacos, where tobacco is made into snuff and cigars, employs 4500 hands, principally females. The Plaza de Toros can accommodate upwards of 12,000 spectators. There is regular communication with Cadiz by river and rail. There are here several royal foundries and factories for arms, and porcelain and iron and machine works. Weaving, soap-making, and other branches of manufacture are carried on. Pop. 152,000.

The Hispal of the Phœnicians, the Hispalis of the Romans, was corrupted by the Moors into Ishbilliah, of which it is supposed the modern name is a modification. It was a place of great importance in the later period of Roman dominion; became the capital of Southern Spain during the ascendency of the Vandals and the Goths, when it was the scene of two notable church councils (590 A.D. and 619 A.D.); and fell into the hands of the Moors in the 8th c., under whom it rapidly rose to a splendid prosperity, and reckoned 400,000 inhabitants. In 1026, it became the capital of the Moorish kingdom ruled by the Abadides, from whom it passed, in 1091, to the Almoravides, and in 1147, to the Almohades. In 1248, it was taken by Ferdinand III. of Castile, when 300,000 Moors left for Grenada and Africa; and from this time to the removal of the court to Valladolid, in the reign of Charles V., S. was the capital of Spain. The city rose to its climax of prosperity after the discovery of the New World, when it became the residence of princely merchants, and the mart of the colonies, but its trade was afterwards transferred to Cadiz. In 1810, it was taken and ravaged by Soult. It capitulated to Espartero in 1843.

SÈVRES, a small town of France, in the dep. of Seine-et-Oise, six miles south-west of Paris, on the Paris and Versailles Railway. It is celebrated for its manufacture of porcelain wares, which gives active employment to 150 persons. S. wares are unsurpassed for elegance of design and beauty of painting. Painted glass is also manufactured. The Porcelain Museum contains a large and curious collection of articles in china and earthenware from all parts of the globe. Pop. (1862) 6328.

SÈVRES, DEUX-, an inland dep. in the west of France, between the deps. Vienne on the east and Vendée on the west. Area 2315 sq. m.; pop. (1866) 333,155. The dep. takes its name from two

rivers of the same name, the Sèvre-Niortaise, which flows west into the sea, and the Sèvre-Nantaise, an affluent of the Loire. It is traversed from south-east to north-west by a chain of hills, called in the south-east the Monts du Poitou, and in the north, the Plateau de Gatine. This ridge forms the water-shed between the Loire on the north and the Charente on the south. The climate is generally healthy, and the soil, two-thirds of which is arable, is very fertile. There are numerous iron mines, and good quarries of freestone and marble. The arrondissements are Niort, Bressuire, Melle, and Parthenay. Niort is the capital.

SEW'AGE. It is of the first importance to health for houses, both in the town and in the country, that all filth should be removed from them as speedily as possible, and disposed of in such a manner as to cease to be injurious to mankind. It may be taken as a pretty safe general guide, that all matters which give off a disagreeable smell are dangerous if allowed to remain near our dwellings; nature thus giving us warning of the presence of something that may do us harm. Many people have thought that if, by using certain deodorising materials, they could either fix this effluvium permanently or for a time, they had surmounted the difficulty; but this is scarcely half a cure, and a palliative like this is much less advisable than a radical measure of removing the filth by suspension in water, and rendering of it not only innocuous, but beneficial, by incorporating it with the great natural deodoriser—the earth. It seems as if nature had planned all this for us, if we will only follow her teaching. During the first two or three days after sewage is deposited in water, the smell is unpleasant, but not dangerous to mankind; after that, putrefaction begins, and the gases given off become deleterious. Here, then, is time for removal, and a punishment for neglect. Fevers, gangrene, ophthalmia, and many other diseases, especially among children, are certain to break out and become malignant if the emanations from such filth exist in the air around human habitations. Until within the last 50 years, privy-pits and cesspools prevailed everywhere. In the country, the former were generally placed in the garden attached to the house, and at some distance off, so that there was not much danger attached to them. In the towns, cesspools existed among the houses, but they were very objectionable and dangerous, and constantly neglected. These cesspools were large underground tanks built in brickwork, into which all the sewage from the house was discharged. In them the filth accumulated and putrified until it was periodically removed by manual labour. They acted like an immense brewing vessel, sending up deadly vapours which had no escape, except back into the house among the inhabitants. The cesspools also frequently leaked, and so if any wells were near, poisoned the water. When Bramah invented the water-closet, and a larger supply of water had to be found for towns, the cesspools began to overflow at such a rate, that a general revision of the whole system became necessary; and at the same time, medical men insisted upon the continuous and perfect removal of filth as the only reliable sanitary process of dealing with the matter. A return to the use of cesspools in any form would therefore be a step in the wrong direction, and would lead to disastrous results.

We may divide the subject as follows: 1. The Management of the Sewage of Cottages; 2. Dwelling-houses and Public Buildings in the Country; 3. Towns; and 4. The Utilisation of Sewage.

1. *Cottages.*—It is obvious that in the case of single detached cottages, expensive arrangements such as those necessary for water-closets could not be provided, and some simpler plan must be followed.

It is very objectionable to allow either cesspool or privy-pit, if they can be avoided, as they are constantly neglected, and overflow into some stream, or poison the wells and the air. The privy should be placed, wherever that can be managed, on the north or east side, and to the rear of the house, so as not to be between the people and the sun and softest winds. The whole sewage-matter should be received in a square galvanised iron pail underneath a seat, which pail can be removed from the outside, and into which a small quantity of house-ashes should be placed, either daily, or as often as the closet is used. This will quite fix the ammonia. The iron pail must be removed by the cottagers at least once a week, and emptied into their garden. No danger can possibly arise from this, if strictly followed, and all the sewage-matter is placed to its best purpose. The sketch attached (see fig. 1) will

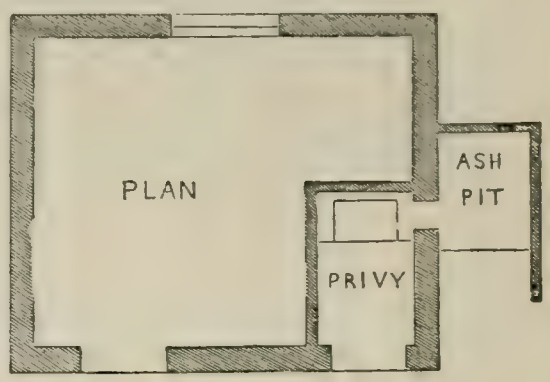


Fig. 1.

shew the way of doing this. There has not been found any difficulty in introducing this system among cottagers.

2. *Dwelling-houses and Public Buildings in the Country.*—It would be useless to discuss a dry-earth system like what has been mentioned anywhere but for outhouses attached to cottages; the general feelings of the inhabitants would not tolerate it. We must therefore accept the water-closet as the system universally adopted. In planning the position of water-closets for a house, the first thing to be thought of is, that they shall be if possible on the north or cool side of the house, and upon exterior walls. If they are placed in the interior of the house, it is troublesome to get at the drains when required, and the closets themselves cannot be sufficiently ventilated. If the closet is inside the house, then Bramah's patent with a D trap underneath is the only form that should be used; but if the closet is outside, then a less expensive one with a syphon earthenware trap may be adopted. It is desirable that the closet should be surrounded with brick walls, and, in fact, isolated from all other parts of the house. The window of the closet when inside the house should always reach the ceiling; and a ventilating shaft in the manner shewn in the accompanying sketch is desirable where the closet is much used, and the window must be shut occasionally. The ordinary water that passes into the drains leading from any closet—such as is discharged each time that the handle is raised—is not sufficient to sweep out thoroughly all the solid matter from the drain-pipes, and therefore a flushing apparatus at the highest point of all sets of drains is essential, so that a body of water may be allowed to pass down with a rush at least twice or three times a week. It is also desirable that the foul air engendered in the drain-pipes themselves should have

some free outlet into the air at some point where it will not be injurious. The gas given off under such circumstances is of a very light character, and has a great tendency to ascend and draw towards heat. During the greater part of the year, especially since the system has been introduced of heating houses by hot air, the temperature of living-rooms is much higher than the atmosphere outside; a pumping action is exercised upon the drains, or indeed upon any outlet, for a fresh supply. If, therefore, some safety-valve is not provided, the gas will force an entry either through the traps or some imperfection in the joints of the drains. The sketch, Fig. 3, will shew the best plan that has yet been devised both for flushing and ventilating the soil-pipes of water-closets. In constructing the drains from houses or large public buildings, it is now a well-decided point that there should be an entirely separate system for the sewage or foul water, apart from that for rain and surface-water. The reasons are many and obvious, but they will be given more appropriately under the head of the Drainage of Towns. Stoneware pipes are the best material to be used for drains, because they are perfectly non-absorbent; but in many cases glazed earthenware will answer very well. The smallest size of pipes of any description that should be used for removing sewage from a house is six inches in diameter. This size, then, may be gradually increased as is necessary, and one of 9 inches will remove the sewage of 500 people. The best fall to be given to a sewage-drain is 1 inch in 10 feet; but all will work well from 1 inch in 5 feet up to 1 inch in 60—provided the flushing arrangements are as they ought to be. In order to keep the drains clean, there must not under 10 gallons of water daily pass down the drain for every person in the house; while anything over 25 gallons is superfluous. At every 20 yards there should be a pipe laid from which the upper half can be removed, and the interior inspected at any time, and any stoppage remedied without the necessity of breaking the pipes. Greasy water, such as is poured down from the kitchen and scullery of a house, is one of the constant causes of such stoppages. The fat, as it cools, congeals on the sides of the pipes, and forms a hard cake. The best method of preventing this is to form a small cesspool, into which the kitchen water is poured first, and then to take an overflow through a syphon into the foul drain, so that the liquid only enters, while the fat can be removed by hand from the cesspool. The sewage matter having been thus all thoroughly removed from the house, a sewage-filter should be built on

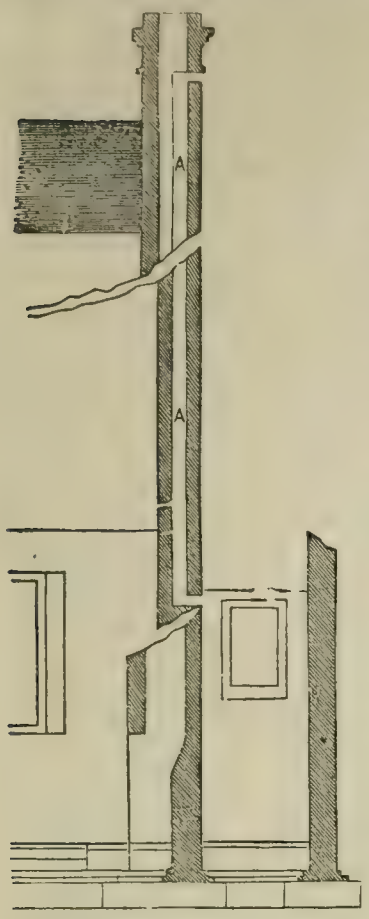

Fig. 2.

AA is the ventilating shaft by which any foul air in the closet itself can pass upwards into the open air. By placing it alongside of a chimney a draught is created which will empty the closet of any effluvium that may be in it.

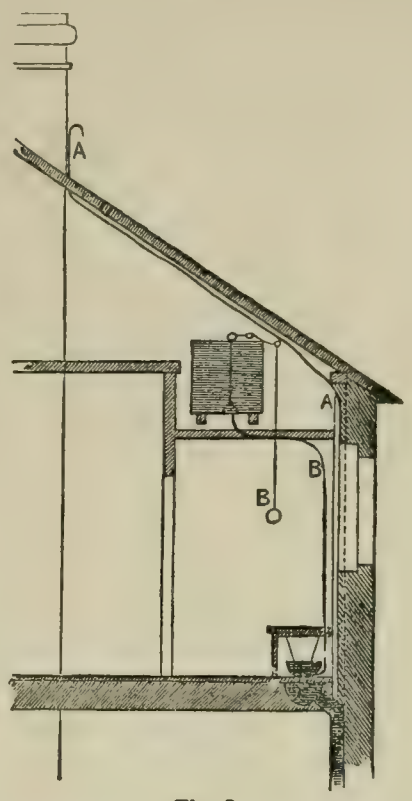

Fig. 3.

AA is the ventilating pipe communicating with the soil-pipe; BB is the flushing apparatus for discharging a quantity of water at once.

the principle shewn in the sketch, Fig. 4. This was originally the design of the Prince Consort. The solid and liquid matters of the sewage are here mechanically separated, and the former can be removed from time to time—say once in six weeks or two months—while the latter must be passed on for irrigation. It is clearly illegal to pass it into

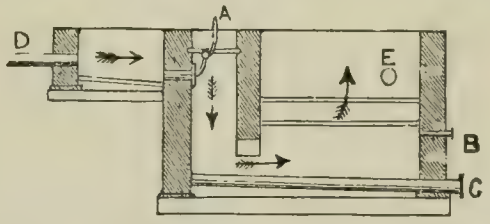

Fig. 4.

The whole sewage matter enters at D; flows in the direction of the arrows; the solid matter becomes arrested in the bottom chamber, while the liquid rises and passes off at E through filtering beds. By opening a tap at B the liquid in the tank or filter can be drawn off, and by opening that at C, the solid matter can be removed. The whole must be water-tight and air-tight. A is a valve for shutting the pipe during cleaning.

any stream; and it is apt to become a serious nuisance if anything else is done with it. We shall treat of the best method of utilising this liquid under the fourth head. It is always advisable to get space for all these arrangements on the north and east side of a house, when possible, so as to run no risk of contaminating the air on the south or hot side of a dwelling; and if a belt of trees can be placed between the sewage-filter and the irrigated land and the house, it will also be advantageous.

3. *The Drainage of Towns.*—Until within the last 30 years, the only drainage which existed in towns was for the rain-water and surface-water

alone, and the inhabitants were strictly watched to prevent their passing any sewage-matter into these drains. The introduction of the water-closet, however, gradually increased the water which overflowed from the old cesspools to such an extent that it was impossible to prevent overflows of this description, and systems of drainage were designed to carry off the whole, both sewage and rain-water. A very composite system of drainage then arose. Generally, the bed of some stream or natural rivulet passing through the town was covered over, and the whole filth passed into that along with the rainfall of the district. This soon was found unsatisfactory, because the flood-waters of the stream were not to be relied on to keep the channel clean, and so the filth remained festering underneath the ground, giving off deadly gases in the midst of the population. The next arrangement which succeeded to that system was to plan large drains for the rain and surface-water, and sewage, and still keeping the idea of the size of the bed of a natural stream before them, engineers thought it necessary to make all the main drains large enough for a man to pass through them, and keep them clean. Seeing the vast quantity of sand and grit that was occasionally washed off the streets, something might be said in defence of this system. Vast numbers of these great main sewers still exist. Into these sewers all the smaller house-drains were to enter, and the surface-water through street-gratings as well. The ordinary water used for domestic purposes, and the occasional rainfalls, were relied upon to flush those large main sewers; but their great size made this an exceedingly difficult and uncertain process, and they, in fact, became only cesspools elongated. In dry weather, the filth was retained in them to such an extent, that after heavy rains, chemical analysis shewed that the water which was discharged contained frequently twenty times the amount of human fæcal matter per gallon more than it did in dry weather. This state of matters, added to the fact that long-continued dry weather was always attended by an increase of deaths from typhus and other fevers, clearly shewed that something more must be done. A further step was then taken by sanitary engineers. The idea of men passing up the drains was set aside, and the smallest possible drains were constructed, until these have arrived at such dimensions as an 18 inch main drain for a town of 10,000 inhabitants. The rainfall was still to be relied on to a certain extent for flushing purposes, but a supplementary assistance was to be given at some points by flushing with water from the ordinary regular supply of the town. As these smaller drains were not sufficient to carry off all the surface and rain-water, as well as the sewage, overflow weirs have been provided at certain points, where the excess must go over, and pass away into some other channel. This is the system now most generally adopted, and is better than its predecessors; but we believe that it, in its turn, must give way to something better, and that before many years. The necessity of dealing with the sewage at the main outfall, and the utilisation of it for agricultural fertilisation, while, in nine cases out of ten, pumping must be employed to lift the sewage of a town at the discharging point for such a purpose, have gradually forced upon us the conviction that the sewage and household water must be kept quite distinct from the surface-water and rainfall.

The outfall of the sewage drain, and subsequent disposal of the filth, are in reality the first things to be considered. Hitherto, engineers in general have taken the nearest stream, and polluted it to such an extent, that perpetual lawsuits, nuisances, and diseases have been the result. Fever of the worst class is certain to follow the drinking of water tainted in this manner, and there is scarcely a stream in the interior of the country which has not been injured more or less from this cause.

Again, where the sewage has been emptied into the sea, tide-locked drains are objectionable, and the sewage, when mixed with salt water, generally gives off more stench than ever. We may briefly say that all attempts at deodorisation by chemical processes have hitherto failed, and as far as our present knowledge goes, are not to be relied upon. The utilisation of the sewage on the fields by irrigation is, therefore, the true solution of the problem, and we must arrive at the simplest, cheapest, most certain, and most perfect system of accomplishing this. When sewage and rainfall all go together in the same drains, as they do in all the older systems, all is uncertainty; while, were the two separated, rain and surface-water can be discharged at any point into the natural water-courses of the country, and a fixed quantity of sewage, with household and flushing water, would be passed to the main outlet, to be there dealt with. The opponents of this system say that it is too expensive and troublesome to plan; that it is unnecessary, as it is sufficient if engineers provide for the dry-weather flow of the sewage, and use that for irrigation; and that when the overflows come into action in floods, the whole is so much diluted, that no harm is done to any one. The advocates of this double system of drainage say that the total separation of the two is the most sanitary system, because the street-gratings and rain-water pipes, which at present let down the rain-water into the sewage-drains, act, in fact, as so many ventilating shafts, and discharge the stench in the midst of the inhabitants; while, under a separate system, the sewage-pipe would be entirely sealed up, and only ventilated at such places as could safely be done; that the rain-water as a flushing-power ought to be entirely discarded, as it fails in dry weather, just when it is most wanted; that in wet weather, and winter again, when the discharging of the sewage on to the surface of land is carried out, the great quantity of water sent down through the drains by the present system is agriculturally a serious injury; that when pumping has to be employed for lifting the liquid for irrigation, as it is in most cases, all is uncertainty, and that no machinery can be economical and efficient under such circumstances, and that the planning of the irrigation also becomes difficult to manage, and irregular. With regard to the expense, it is further maintained that, as the rain-water and surface-water can be discharged at the nearest point, all the drains may be much lessened in size; and further, that the flushing-power of the water in the sewage-drains will be much more efficient, while the corresponding lessening of the expense in carrying out the process of utilisation will completely compensate any additional outlet that may be incurred in laying the drains in towns. If we take the case, which is a common one, of a population of 10,000 people living upon a square mile, the first-mentioned system, where rain and sewage water go together, would require pumping-machinery, in dry weather, of, say, five horse-power, to lift the liquid; and it would further be necessary, for wet weather, to have in reserve a lifting-power of 150 horses; while, on the separate system, where the sewage alone would have to be dealt with, the five horse-power engine would be regularly and constantly employed, and its work would be almost entirely confined to the daytime, whereas the other must be ready at any time, and

for every emergency. The system of sending sewage and rain-water together has been hitherto adopted in all towns; but except in one or two cases where gravitation has been available to utilise the discharge from the drainage, all engineers have failed to prevent the pollution of rivers, and it is obvious that something else must be tried, as that cannot be permitted to go on much longer. The system of separating the sewage and rain-water has been carried out in several large asylums and public buildings, with their attendant houses, and the sanitary results have been thoroughly satisfactory; while the utilisation has been, in consequence, completely carried out, and is manageable at all seasons and in all weathers. Within two or three years, it will also be accomplished in some towns, and the public can then judge between the two.

4. *The Utilisation of Sewage.*—The whole of the sewage of a house or town having been conveyed away in the manner we have described, the next important step is to know what to do with it. Above all things, it is desirable to add to the productiveness of the soil, so as to compensate in some degree for the constant supply we are drawing from that source.

The liquid nature of sewage, adopting as we may the ordinary amount of dilution in dry weather at the rate of 25 gallons per head, has been a great obstacle in the way; while also the vast quantities of road-grit, and the great gluts of rain that come down along with the sewage when there is only one system of drains in a town, have upset all arrangements and calculations. Many attempts have been made, especially at Leicester, some years ago, to precipitate all the valuable qualities of the sewage by impregnating the whole with milk of lime; but the process was unremunerative to those who did it, as so much sand was precipitated at the same time, that the product obtained was almost worthless as a manure; while, as the greater part of the ammonia escaped in the water, the discharging of it into any stream was still, strictly speaking, quite illegal. As far as chemical knowledge can guide us, there seems at present to be no hope in this direction.

At Edinburgh, again, and at Croydon, the irrigation of land by gravitation has rendered the process a simple one, because the whole has been poured over the land with many excellent results. These, however, are clearly exceptional cases, and we must look to pumping as being necessary in by far the greater proportion of towns; while for the two places we have mentioned, the results would, in all probability, have been better still if the strength of the sewage had been more concentrated. Agriculturally speaking, any dilution above 25 gallons per head of the population is not desirable, but is injurious and expensive to distribute; while, again, human fæcal matter is too strong to be applied to land unless diluted in something like ten gallons of water. The Chinese teach us an important lesson in this respect. They place all the solid matter, when they remove it from the towns, in small wells in their fields, and then take a scoopful and mix it in about ten or twelve times its volume of water before they apply it to their crops. If any one attempts utilising sewage when mixed with rain-water, and has to pump the whole all the year through, he will find himself in endless difficulties.

Presuming, then, that we can arrive at a fixed quantity of 20 gallons per head of the population, or what may be taken as the dry-weather flow of the drainage from a town, the first step is to pass the whole through an upward filter, so that all materials may be intercepted which will be likely to interfere with the pumping, or choke the smaller pipes used for irrigation. This is necessary, also, because in its unfiltered state we cannot depend upon sewage going down and up again, and so passing over a valley, and the sphere of operations then becomes more limited.

Great part of the solid matter can also be removed by this process, and common house-ashes are the best mixing and deodorising material to facilitate the stuff being carried away.

A piece of land should then be sought out, with a slope, if possible, of one foot in 30 at least, and the filtered liquid, which will be full of strength, conveyed either by pumping or gravitation to the highest point of that land. Iron pipes should not be used, if possible; but when the land to be irrigated is very flat, they must be. From the highest point of the land selected, the liquid must be conducted by open channels or through common drain-pipes laid on to the surface to all the different points where it is wished, and utilised for irrigation. The land adopted should be moderately porous, and then for every 100 people an acre may be allowed, but this varies much according to the nature of the soil. The land must be thoroughly drained and prepared. The best crops to be grown are Italian rye-grass, with alternately crops of vegetables, such as potatoes, cabbages, rhubarb, mangold. All these will luxuriate on the liquid, and we think we may safely say that the command of such liquid would be worth to any person from £5 to £10 an imperial acre, according to local circumstances.

Milch cows thrive remarkably well on this grass, and it has been proved by chemical analysis that the milk is of the best quality, while the vegetables are also peculiarly wholesome.

Could such a system be carried out in the neighbourhood of all our large towns, the results would be highly beneficial. The difficulties in the way, principally arising from ignorance on the subject, have been great; but to this system, or something like it, there can be no doubt, before many years, we must come, to prevent pollution of the rivers, and to make the most of the sources of fertility which are at our command, but which we are at present recklessly wasting. Many committees have been appointed by the House of Commons to inquire and take evidence on this subject. In 1857, a commission was issued by the crown to certain gentlemen, at the head of whom was Lord Essex, to inquire into 'the best mode of distributing the sewage of towns, and applying it to beneficial and profitable uses.' This commission went to work principally at Rugby, and have made a vast number of experiments, the general result of which may be stated to be, that ordinarily diluted sewage may be said to produce such increased crops as to warrant an agriculturist in giving one halfpenny a ton for it, a ton of water containing 224 gallons. The third Report was issued in April 1865, and the following recommendations are given as the results of their labour:

'1. The right way to dispose of town-sewage is to apply it continuously to land, and it is only by such application that the pollution of rivers can be avoided.

'2. The financial results of a continuous application of sewage to land differ under different local circumstances; first, because in some places irrigation can be effected by gravity, while in other places more or less pumping must be employed; secondly, because heavy soils (which in given localities may alone be available for the purpose) are less fit than light soils for continuous irrigation by sewage.

'3. Where local circumstances are favourable, and

undue expenditure is avoided, towns may derive profit, more or less considerable, from applying their sewage in agriculture. Under opposite circumstances, there may not be a balance of profit; but even in such cases a rate in aid, required to cover any loss, needs not be of large amount. Finally, on the basis of the above conclusions, we further beg leave to express to your Lordships that, in our judgment, the following two principles are established for legislative application: First, that wherever rivers are polluted by a discharge of town-sewage into them, the towns may reasonably be required to desist from causing that public nuisance. Second, that where town-populations are injured or endangered in health by a retention of cesspool-matter among them, the towns may reasonably be required to provide a system of sewers for its removal; and should the law as it stands be found insufficient to enable towns to take land for sewage-application, it would, in our opinion, be expedient that the legislature should give them powers for that purpose.'

It is obvious, however, to any one perusing the above paragraphs, that they are exceedingly vague, and form but little guide to any one who must go into the question of whether money invested in utilisation of sewage-schemes will pay an adequate return upon the outlay. The uncertainty attending the dilution of the sewage; the necessity of making the earth take it at all seasons; the distance that the liquid has to be pumped—have all been such difficulties in the way, that the commission could not well arrive at any other result than they have done.

The presumption would therefore seem to be a very strong one, that, until we arrive at fixed quantities, no reliable principles can be laid down that would in all cases enable us to overcome the difficulties attending the sanitary management and utilisation of sewage.

SEWARD, William Henry, American statesman, was born at Florida, New York, May 16, 1801, of Welsh and Irish descent. His father was a physician and merchant, who, after accumulating a moderate fortune, was appointed judge of one of the inferior courts. S. entered Union College at 15; in 1819, he visited the south, and was engaged for six months as a school teacher in Georgia. Called to the bar in 1822, he settled at Auburn, Western New York, and became the partner and son-in-law of Judge Miller. In 1825, his political abilities were manifested in an oration delivered at Syracuse, and in 1828 he was chosen president of a state convention. At this period, New York was the centre of a wide-spread excitement against Freemasons, and S., as a leading anti-mason, was elected to the state senate. In 1833, he visited Europe, and wrote a series of letters, which were published in the *Albany Evening Journal*. In 1834, he was a candidate for the office of governor of New York, but was defeated by the democratic candidate. About this time he received the lucrative appointment of agent of the Holland Land Company, which gave him wealth and influence. In 1838, he was elected governor of New York. In this position, he recommended the increase of education, internal improvements, a liberal policy toward foreign immigrants, and took the side of abolition in the growing controversies on slavery. In 1849, he was elected to the senate of the United States, where he became the acknowledged leader of his party, and in the debate on the admission of California he promulgated what was called his 'higher-law' doctrine, in saying that there was 'a higher law than the Constitution which regulated the authority of Congress over the national domain—the law of God, and the interests of humanity.' In a speech at Rochester, N. Y., in 1858, he declared that there was 'an irrepressible conflict between opposing and enduring forces,' and that 'the United States must become either entirely slave or entirely free.' In 1859, he revisited Europe, and extended his tour to Egypt and the Holy Land, and in 1860 was the most prominent candidate of the republican party for nomination for the presidency. Mr S. accepted the important post of Secretary of State under President Lincoln, and guided the diplomacy of the Federal government through the perils of the War of Secession with an almost unparalleled energy and success. On the invasion of Mexico by the French in 1862 he persisted in recognising the government of Juarez. In 1865 he declared the attempt to establish a foreign and imperial government in Mexico to be disallowable and impracticable. The French army was accordingly withdrawn in 1866, and Napoleon III. humiliated by the failure of his enterprise. On the 14th of April, 1865, President Lincoln was assassinated by John Wilkes Booth, and at the same time another assassin, named Payne, penetrated to the room of Mr S., dangerously wounded his son, and with a poignard inflicted wounds upon Mr S. which were at first believed to be fatal, but from which he slowly recovered. He retained office under Andrew Johnson, and supported his policy relating to reconstruction against the almost unanimous sentiment of the Republican party, thus giving great offence to his former friends. In 1868—1869 he made a voyage to Alaska, the purchase of which he successfully advocated, and visited California and Mexico on the route. In 1870—1871 he visited Japan, China, and Egypt, being everywhere received with distinguished honors. The Mikado of Japan gave him a private audience, an honour never before accorded to a foreigner. S. is universally admitted to be one of the ablest and most accomplished of living American statesmen. Mr S. has written a life of John Quincy Adams, a life of De Witt Clinton, and numerous speeches.

SEWING-MACHINE, one of the most important inventions of this century. Like the stocking-frame, which in principle it closely resembles, we owe it to the ingenuity of a poor mechanic, striving to lessen the labour of his wife and other poor women. Elias Howe, a native of Massachusetts, devoted his evening leisure hours to the construction of a sewing-machine. This was about the year 1841, and his career since that period up to the present time forms a striking chapter in the annals of intelligent labour, and furnishes another proof of the saying that 'fact is stranger than fiction.' After incessant labour, during the latter part of which he and his family were indebted to a friend for the means of subsistence, he completed the first working sewing-machine, the patent for which was granted to him in May 1841. He did not succeed in inducing the people of his own country to see the value of his patent, and came to England, where, after patenting it here also, he met with so much discouragement that he sold the patent for £250 and a royalty of £3 per machine to a staymaker, Mr Thomas of Cheapside, London, who used it successfully in his own business, but did so little towards making it public that for several years its existence was only known to a very few individual manufacturers. When Howe reached his own country again, he found his American patent pirated by a wealthy company; but with admirable spirit he asserted his rights, and succeeded in establishing them; and it is gratifying to know that his talent, industry, and perseverance have been rewarded, for he became a wealthy man. Howe's machine worked what is called the lock-stitch, but since his invention became known, several improvements and modifications have been introduced by

other inventors. The principal of these are as follows: 1. *Machines which sew with one thread;* of which one kind makes the *through-and-through*

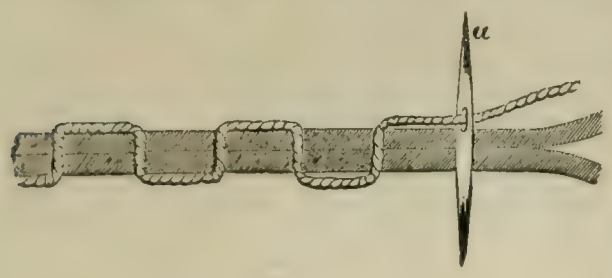

Fig. 1.

or *shoemaker's stitch* (fig. 1), the thread being held and pushed through with pincers, one pair on each side of the material to be sewn. The needle, *a*, is pointed at each end, and being pushed through by the pincers on one side, is taken hold of by the corresponding pair on the other, and the thread is thus pulled through backwards and forwards. Only a small length of thread can be used by this machine, hence it is of but limited application. 2. Another single-thread machine makes the *running-stitch* (fig. 2). In this, the needle, *a*, is stationary,

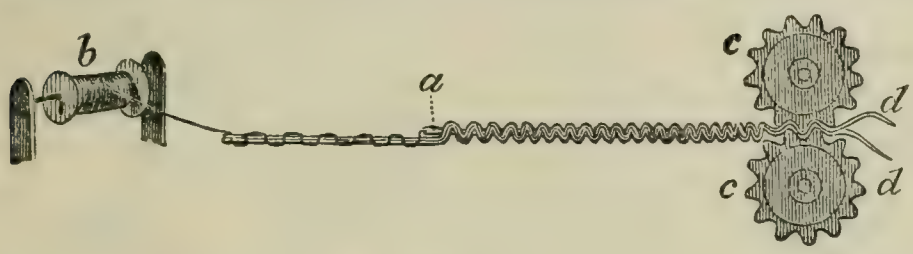

Fig. 2.

and receives a continuous supply of thread from a reel, *b;* the two small-toothed wheels, *c*, *c*, are so arranged that their teeth, pressing into one another, crimp the two pieces of cloth, *d*, *d*, and push them

Fig. 3.

forward against the point of the needle, which, as it gets filled, is relieved by the operator, who keeps drawing the sewn cloth off at the eye-end

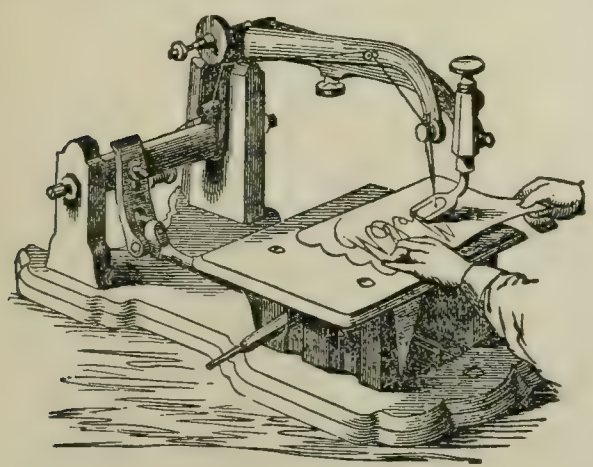

Fig. 4.

of the needle. This machine answers admirably in cases where loose tacking is required. It is the invention of an American of the name of Bostwick, who introduced it into England in 1844. 3. The *chain* or *tambour stitch* is also a single-thread stitch (fig. 3), the machine for which was invented by M. Thimmonier, a Frenchman, in 1848. In this, the thread is looped upon itself by means of a

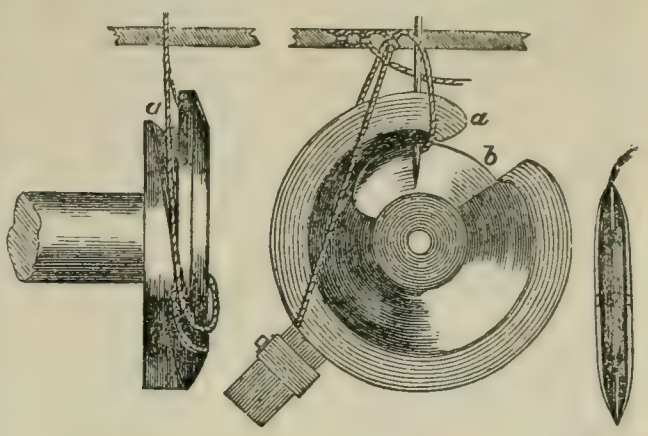

Fig. 7. Fig. 5. Fig. 6.

curved shuttle after it has passed through the cloth This kind of stitch, though very useful for some kinds of work, is easily pulled out. 4. Fig. 4 represents Wheeler and Wilson's sewing-machine, another American invention, which has acquired the greatest reputation in Great Britain. It is a double-thread machine, and besides the vertical eye-pointed needle, has a curved shuttle or hook (fig. 5, *a*) working below, with a revolving reel, *b*, inside its curve. The reel is of metal, each side being convex externally; and so adjusted on the axle, that the edges are so near together as to admit only one thickness of the thread to pass through (fig. 6). The side view of the whole arrangement is seen in fig. 7. It fits easily within the nearly circular hook, and gives off its thread as required. The thread passes partly round the outer edge of the hook upon a slightly-grooved bevel (*a*, fig. 7), which forms a loop, and passes it between the needle and the thread which it carries with it in descending; the loop is held in position as the needle ascends, and the cloth being moved on, the next descent of the needle takes it through the loop and receives another below it, which renders the first one tightly locked, as in fig. 8. For such work as male and female dressmaking generally, this kind of machine is at present unrivalled, both for the efficiency of its work, and also for the neatness and

Fig. 8.

finish of the machines made for private use. The magnitude to which the manufacture of sewing-machines has attained in the United States will appear by the return of the manufacturers for the year 1870 to the owners of the leading patents on which they pay a royalty. The Singer Manufacturing Company, 127,833; Wheeler & Wilson, 83,208; Howe, 75,156; Grover & Baker, 57,402; Weed, 35,002; Willcox & Gibbs, 28,890; American Button-hole, &c., 14,573; Florence, 17,660; and all others, 24,530; a grand total of 464,254 machines made in one year.

SEXAGE'SIMA SUNDAY (Lat. *sexagesima*, i. e., *dies*, the sixtieth day), the second Sunday before Lent, and roughly reckoned the sixtieth day before Easter.

SEXAGES'IMALS, a mode of arithmetical calculation introduced by the ancient Greek astronomers, especially by Ptolemy (q. v.), into astronomical and geometrical reckoning. It was founded upon the division of the circle into 360 parts, and the radius being nearly $\frac{1}{6}$th of the circumference, was considered to contain 60 of these parts or degrees. Continuing the same mode of subdivision, each degree (°) on the radius was divided into 60 minutes (′), each minute into 60 seconds (″), and thirds (‴), fourths (⁗), &c., followed in the same relation to each other. Addition and subtraction are not altered in this method, but multiplication, division, and the extraction of roots are so to a considerable extent. Multiplication, the most used of these three operations, was carried on in the descending scale, as in the following example, where λα° ὸ′ κζ″ is to be multiplied by κθ° ιη′ νδ″, or (substituting Arabic numerals) 31° 4′ 27″ by 29° 18′ 54″:

31°	4′	27″			
29°	18′	54″			
899°	116′	783′			
	558′	72″	486‴		
		1674″	216‴	1458⁗	

899° 674′ 2529″ 702‴ 1458⁗ = 910° 56′ 21″ 6‴ 18⁗

Here, each of the three numbers, 31, 4, 27, is multiplied by 29; the same three by 18, and the results placed in the line below, one step to the right; and again by 54, and the results placed another step to the right. This arrangement proceeds on the principle that the product of degrees by minutes gives minutes; of minutes by minutes, seconds; of minutes by seconds, thirds; and, in general, the denomination of a product is indicated by the sum of the marks superposed on the two factors. The columns are added and rearranged by Reduction (q. v.). This system, though clumsy and intricate, was a great improvement, as regards facility and accuracy, on the former Greek method; and so much was it admired, that succeeding geometers founded on it a complete system of general calculation, and a work on sexagesimal computation was written by Barlaam (q. v.), who died in 1348. It is almost unnecessary to state, that the terms minutes, seconds, thirds, &c. here employed only denote sixtieths, sixtieths of sixtieths, &c., and *have no other signification;* further, that the degrees, minutes, and seconds in the multiplier are, for the time being, merely abstract units and parts of units. The operation of modern arithmetic known as *duodecimal multiplication* is effected in the same way, the subdivisions being twelfths in place of sixtieths.

SE'XTANT, an instrument for measuring the angular distance of objects by means of reflection. The principle of its construction depends upon the theorem, that *if a ray of light suffer double reflection, the angle between the original and the direction after the second reflection is double of the angle made by the reflecting surfaces.* Thus let A and B (fig. 1) be two mirrors perpendicular to the same plane, and inclined to each other, and let SA be a ray of light, which falling upon A is reflected on B, and re-reflected in the direction BC, then ACB is the angle between the original and finally reflected rays, and ADB is the angle between the mirrors. Now, as the angle of reflection is equal to the angle of incidence $\angle SAF = \angle BAD$, and $\angle GBA = \angle DBC$; but $\angle EBC = \angle BAC + \angle BCA = (\angle BAD + \angle DAC) + \angle BCA = (\angle BAD + \angle SAF) + \angle BCA = 2\angle BAD + \angle BCA$; and $\angle EBC$ also $= \angle EBD + \angle DBC = \angle EBD + \angle GBA = 2\angle EBD = 2\angle BAD + 2\angle BDA$; therefore $\angle BCA = 2\angle BDA$, which proves the truth of the theorem. The instrument of which this theorem is the principle is a brass sector of a circle in outline; the sector being the sixth part of a complete circle, for which reason the instrument is called a *sextant.* Fig. 2 shews the essentials of its construction; AMN is the sector whose curved side, MIN, is the sixth part of a circle; A is one mirror wholly silvered, placed perpendicular to the plane of the sector, and on, and in line with, the limb AI, which is movable round a joint at or near A; B is the other mirror, also perpendicular to the plane of the instrument, and silvered on the lower half only, the upper half being transparent; E is an eyelet-hole or small telescope. The graduation runs from N to M (on a slip of silver, platinum, or gold let into the rim), and is so adjusted that when the movable limb is drawn towards N till the mirrors A and B are parallel, the index, which is carried at the foot of the movable limb is opposite zero on the graduation. If we suppose that this zero-point is at N, it is evident that the angle between the mirrors is equal to the angle NAI; and again, if instead of graduating from 0° at N to 60° at M, which is the proper graduation for the sixth part of a circle, the graduation be made from 0° to 120°, that is, each half degree being marked as a degree, and similarly of its aliquot parts, then the angle NAI, read off by the index at I, will shew at once the angle between the incident and finally reflected rays. The mode of using the sextant consists in placing the eye to the telescope or eyelet-hole, and observing one object directly through the unsilvered part of B, and then moving the index till the image of the other object, reflected from A upon the silvered part of B, coincides with, or is opposite to the first object, then the angle, read off at I, gives the angle between the objects. For additional accuracy, a vernier is attached to the foot of the movable limb.

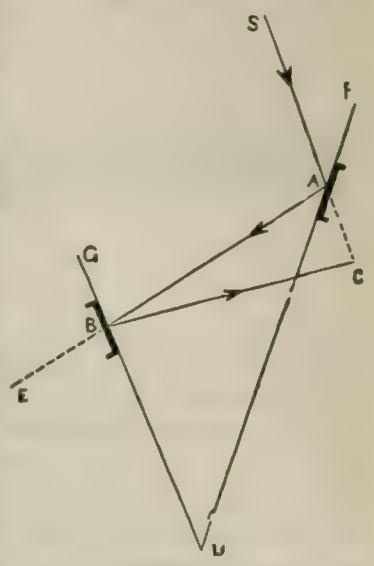

Fig. 1.

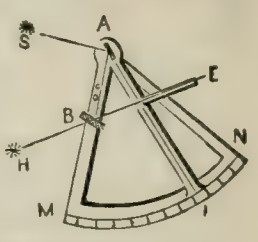

Fig. 2.

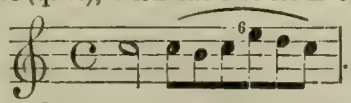
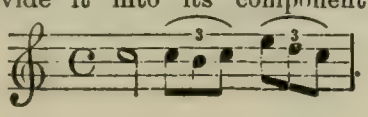




The sextant is capable of very general application, but its chief use is on board ship to observe the altitude of the sun, the lunar distances, &c., in order to determine the latitude and longitude. For this purpose, it is necessary to have stained glasses interposed between the mirrors A and B, to reduce the sun's brightness. These glasses (generally three in number) are hinged on the side AM, so that they may be interposed or not at pleasure. B is the glass through which the horizon is perceived, and has hence received the name of the *horizon-glass;* while the other mirror, from its being attached to the index-limb, is called the *index-glass.*

The sextant is liable to three chief errors of adjustment; 1° if the index-glass be not perpendicular to the plane of the instrument; 2° if the horizon-glass be not perpendicular to the plane of

the instrument; and 3° if, when the mirrors are parallel (which is the case when a very distant body, such as the sun or moon, is observed directly through B, and found to coincide with its image in the lower part of B), the index does not point accurately to 0°; this last is called the *index-error*, and is either allowed for, or is remedied by means of a screw, which moves the index in the limb AI, the latter being stationary. The first two errors are also frequently remedied by means of screws working against a spring, but in the best instruments the maker himself fixes the glasses in their proper position.—The *quadrant* differs from the sextant only in having its arc the fourth part of a circle, and being consequently graduated from 0° to 180°; the *octant* contains 45°, and is graduated from 0° to 90°; while the *repeating-circle*, which is a complete circle, is graduated from 0° to 720°. A common form of the sextant is the 'snuff-box' sextant, which is circular in shape, and as it can be conveniently carried in the pocket, is the form most frequently used by land-surveyors.

The idea of a reflecting instrument, on the principle of the sextant, was first given by Hooke about 1666; but the first instrument deserving the name was invented by John Hadley (q. v.) early in the summer of 1730, and a second, and much improved form of it, was made by him a short time afterwards. Halley, at a meeting of the Royal Society, claimed for Newton the priority of invention; and in October, 1730, a Philadelphian, Thomas Godfrey, also asserted his claim as the original inventor, but that learned body decided that Newton's claim was unsupported by even probable evidence, and that Hadley's and Godfrey's inventions were both original, but that the second form (which is almost the same as the common sextant now employed) of Hadley's instrument was far superior to his first form and to Godfrey's.

SE'XTON (corrupted from SACRISTAN, q. v.), is a parochial officer in England, whose duty is to take care of the things belonging to divine worship. He is usually chosen by the inhabitants, but often also by the minister or the churchwardens, the mode of appointment being regulated by the custom of each parish. He sometimes also holds the office of parish-clerk. Women have occasionally been appointed sextons, this being one of the offices which women may fill, and they also have a vote in elections. The office is a freehold office for life, except in the new parishes under Church-building Acts; the duty is to keep the church clean, swept, and adorned; to open the pews; to make and fill up the graves; to prevent any disturbance in church. The salary is paid by the churchwardens, and as to amount depends on custom. In Scotland, the beadle performs similar duties, and is appointed by the heritors.

SE'XTUPLET, in Music. When a note is divided into six parts instead of the usual division into four—as, for instance, a minim into six quavers, or a crotchet into six semiquavers—the group is called a sextuplet, and the figure 6 is generally placed above it. The proper sextuplet is composed of three groups, of two notes each, being, in fact, a Triplet (q. v.), with each of its notes subdivided into two:  . But a group composed of two successive triplets is sometimes, though not very correctly, also called a sextuplet, and written as such, though it is more correct to divide it into its component two triplets, thus:  .

SEYCHE'LLES COCOA-NUT, or DOUBLE COCOA-NUT (*Lodoicea Seychellarum*), a palm, of which the fruit has some resemblance to a cocoa-nut, although it belongs to a different tribe of palms, being allied to the Palmyra Palm. It is found only in the Seychelles Islands; and the fruit, wafted by the winds to the shores of the Maldive Islands, or found floating in the Indian Ocean, was long the subject of many ridiculous fables, and is still an object of interest and curiosity, and as such one of the minor articles of commerce. The tree grows to the height of 50 or 60 feet, with a tuft of immense leaves. The wood and the leaves are used for a variety of purposes, like those of other palms. The 'cabbage' or terminal bud is eaten. The fruit is often a foot or a foot and a half long, in shape like a melon, its outer husk green, the interior near the base divided into two parts, at first filled with a white sweet jelly, which changes into a white horny kernel. The shells are used for making vessels of various kinds, often beautifully carved and ornamented.

SEYCHE'LLES ISLANDS, situated nearly in the centre of the Indian Ocean, between 3° 40′—5° 35′ S. lat., and 55° 15′—56° 0′ E. long., a group of more than thirty isles, resting on an extensive bank of sand and coral, and forming the most important of the dependencies to the colony of Mauritius. The principal are Mahé, Praslin, Silhouette, La Digne, Curieuse, St Anne, Aux Cerfs, Frégate, Marianne, Longue, and Du Sud Est. Mahé, the most considerable and populous of the group, and the seat of government, is 18 miles long, and from 3 to 5 broad. The islands are mountainous, often rising abruptly from the sea, and are clothed with the most luxuriant verdure; one of the peaks, named Mont Blanc, in Mahé, attains an altitude of 2000 feet. The principal port is Victoria, on the north-eastern side of the island of Mahé, the houses of which are chiefly built of wood, and are much subject to the ravages of the white ant.

The S. were known to the early Portuguese navigators, who bestowed on them the title of Isles de Mascarenhas; subsequently, the French renamed them Iles La Bourdonnais, and finally changed their appellation in honour of the Count Herault de Seychelles. The S. were among the earlier discoveries of the Portuguese, after the accomplishment of their first voyage to India. They were first settled by the French in 1756, who commenced the cultivation of spices, under circumstances so favourable as to induce a belief in a lucrative competition with the more easterly colonies of the Dutch. The immunity of the S. from the hurricanes which periodically visit the neighbouring seas, rendered them peculiarly suited for this purpose, which was only defeated by the suicidal destruction of the spice-plants by the French occupants, to prevent their falling into the hands of the English in 1778. On the cession of Mauritius, the S. were finally taken possession of by Great Britain. The islands produce a large quantity of timber suitable for ship-building purposes; and the S. cocoa-nut, which is indigenous only in the S., and the nuts, leaves, &c. of which are applied to a great variety of domestic purposes by the natives. Sugar was formerly cultivated. Cotton flourishes here, and is now being brought into notice as a staple export. Cocoa-nut oil and tortoise-shell are also among the articles of commerce; but the want of labour is the great obstacle to a more general development of these naturally fertile isles. The introduction of coolie labour from India is now under consideration, and, combined with the present rapid steam-communication to Suez, would tend greatly to place the S. in the forward position which their important geographical situation fully warrants.

The population of the S., as taken at the last census (1861), was 7486 souls, 700 of whom are employed in the shipbuilding yards and factories.—See Sir Edward Belcher's *Account of the Seychelles: Voyage of H. M. S. Leven and Barracouta*, by Captain Owen, R. N.

SEYMOUR, FAMILY OF. This family, whose history is largely interwoven with that of England, was originally settled at St Maur—whence its name—in Normandy. Coming over to England, the Seymours obtained lands in Monmouthshire as early as the beginning of the 13th century. They acquired estates at Hatch Beauchamp, Somersetshire, by marrying an heiress of the Beauchamps early in the 15th century. In 1497, we find the head of the family, Sir John Seymour, employed in suppressing the insurrection of Lord Audley and the Cornish rebels, and subsequently accompanying King Henry VIII. to his wars in France, and to the Field of the Cloth of Gold. Of the issue of this worthy knight one daughter became the wife of Henry VIII., and mother of Edward VI.; one son, Thomas, created Lord Seymour of Sudeley, became Lord High Admiral of England, and the second husband of Henry's widow (Catherine Parr), and ended his life on the scaffold, being attainted of high treason. Sir John's eldest son, Edward, who held many high positions in the court of Henry, was created Lord Seymour of Hache, and Duke of Somerset in 1546—1547. He had been sent into France by Henry to settle the disputed question of the border of the English possessions there, and secured the confidence of the king so far, that he was left by him one of his executors and one of the council of the young Prince Edward. He was subsequently made Lord High Treasurer, and eventually 'Protector and Governor of the King and his realms.' (See EDWARD VI.) His subsequent fall, after a two years' tenure of his all but regal power, by the influence of Dudley, Earl of Warwick and Duke of Northumberland, was followed by an attainder of his honours, which was not reversed for more than a century. The eldest son of the Protector by his second marriage, being created by Elizabeth Earl of Hertford, married the Lady Catharine Grey, a grand-niece of Henry VIII., sister of the unfortunate Lady Jane Grey—a marriage which entailed on him a long imprisonment and a heavy fine. His grandson, who succeeded him in the Earldom of Hertford, was also sent to prison in the Tower of London for marrying the Lady Arabella Stuart, cousin of James I. of England; but subsequently, playing a conspicuous part in the royal cause in the civil wars, obtained in his own favour a reversal of his ancestor's attainder (see above), and in 1660 took his seat in the House of Peers as second Duke of Somerset, although the descendants of the first duke, by his first marriage, were then in existence. He died in 1675, and his ducal title passed to a cousin, on whose death it was inherited by Charles Seymour, known in history as the 'Proud Duke of Somerset,' a nobleman whose style of living was ostentatious and haughty in the extreme, and who filled several high posts in the courts of Charles II., William III., and Anne. He married the heiress of the Percies, by whom he had a son, Algernon, 7th duke, who was created Earl of Northumberland, with remainder to his son-in-law, Sir Hugh Smithson, the ancestor of the present Percy line. On the death of this duke, a curious peerage case arose, the title being claimed by the descendants of the first duke by his first marriage, on the failure of the younger branch; and the attorney-general having reported in favour of the claim, Sir Edward Seymour took his seat in the House of Peers as 8th Duke. From him the present holder of the title is third in direct descent.

SEYNE, LA, a small but rapidly increasing seaport of France, on the shore of the Mediterranean, in the dep. of Var, three miles south-west of Toulon. Fishing and navigation are the chief employments. Pop. (1856) 6419, (1862) 9070.

SE'ZZÉ, or SEZZA, a city of Central Italy (Papal States), legation of Velletri, with 8000 inhabitants. It is a very ancient city, and still preserves some remains of a triple wall of Cyclopean architecture, which surrounded the rock on which it stands.

SFORZA, a celebrated Italian family, which played a most important part in the affairs of Italy during the 15th and 16th centuries, swayed the destinies of Northern Italy for many years, and allied itself with the first sovereign houses in Europe. Its founder was a peasant of Cotignola, in the Romagna, by name *Giacomo*, or *Muzio* (sometimes combined by historians into *Giacomuzzo*) *Attendolo* (born 1369), who deserted his trade of wood-cutting to become a 'condottiere,' and by his intelligence and courage rose to a high position in the band to which he belonged. Count Alberigo de Barbiano, the founder of Italian 'condottierism,' bestowed upon him, on account of his prowess, the name of SFORZA (Ital. 'the forcer'); and such was his reputation among his comrades, that he speedily found himself the independent leader of a band of condottieri, and offered his services to the king of Naples. Queen Joanna II. made him constable of that kingdom, and in exercise of his office, he chased away the Aragonese, and others, who attempted to deprive her of her dominions; but dying soon after (4th January 1424), he left his devoted followers to the chieftainship of his natural son, FRANCESCO S., then 23 years of age, who was as brave and enterprising as himself. Francesco, as was the custom of the time, sold his sword to the highest bidder, and without the slightest scruple fought for or against the pope, Milan, Venice, and Florence. He invented an improved system of tactics, and it soon came to be taken for granted that victory was certain for the party which he supported. It was thus no great act of condescension in the Duke of Milan, the haughty Visconti, to confer upon him the hand of his daughter, Bianca, with Cremona and Pontremoli as a dowry, and the promise of succeeding to the duchy itself. Meantime, S. took the march of Ancona from the pope (1434), added to it Pesaro (1443), and by a judicious combination of force and stratagem, obtained his elevation to the dukedom of Milan (26th February 1450), after the decease of his father-in-law. He solidly established his authority over all Lombardy, and several districts south of the Po; acquired the esteem of Louis XI., who gave up to him Savona and Genoa; and after gaining the universal love of his subjects, died 8th March 1466. Though uninstructed, he possessed considerable eloquence, and loved and protected letters. The successors to his power possessed few or none of his distinguished talents. His son, GALEAZZO-MARIA S. (1466—1476) was a true tyrant, gloating over the torments of his victims, and a monster of debauchery, prodigality, and ferocity, without a single redeeming feature in his character. He was assassinated (26th December) at the porch of the cathedral of Milan. His son GIOVANNI-GALEAZZO S. (1476—1494) succeeded, under the regency of his mother, Bona of Savoy, who held the reins of government with a firm hand. But she was forced to give up (1480) her able coadjutor, Simonetta, to the vengeance of her brother-in-law, Lodovico Maria, surnamed 'the Moor,' from his black complexion; and three days

after Simonetta's execution, the ambitious Lodovico banished herself, and assumed the regency. Finding the young duke in his way, Lodovico put him and his wife, Isabella of Calabria, in prison, and was immediately threatened with attack by the king of Naples, a danger which he attempted to ward off by giving his daughter, Bianca, with a dowry of 400,000 ducats, to the emperor Maximilian I., and by stirring up Charles VIII. of France to assert his claims to Naples. Soon afterwards, Duke Giovanni-Galeazzo died, poisoned, as some believe, by his uncle, 20th October 1494. LODOVICO-MARIA (1494—1500) obtained his investiture as duke, and becoming alarmed at the rapid progress of the French in Italy, he joined the league against them, and was rewarded for his perfidy by being driven from his duchy, which was seized by the troops of Louis XII. (1499). The following year he made an ineffectual attempt to regain possession, was made prisoner, and carried to France, where he died in 1508. He possessed great talents, combined unfortunately with a low morality, which led him to value astuteness more than everything else; but his encouragement of letters and of the fine arts, will preserve his name to posterity. His eldest son, MASSIMILIANO S. (1512—1515), regained the duchy of Milan after the reverses suffered by Louis XII., and with the aid of the Swiss steadily repulsed the various energetic attempts of the French to recover it; but after the battle of Marignan (1515), he abandoned his rights to the French for a pension of 30,000 ducats, glad to be free from the insolence and exactions of his allies, and the attacks of his enemies. His brother, FRANCESCO-MARIA S., succeeded nominally to the Milanese after the battle of Pavia, but he was a mere puppet in the hands of Charles V., and on his death, 24th October 1535, and the extinction of the main line of the house of S., the duchy was quietly swallowed up by Austria. The Lords of Pesaro (extinct in 1515), the Counts of Santa-Fiora, in Tuscany, still existing, and the Dukes of Sforza-Cesarini, descend from collateral branches of the family.

SFORZA'TO (Ital. forced), in Music, often contracted *sf*, a term used to indicate that the note over or under which it is placed is to be played with strength and emphasis. A higher degree of emphasis is indicated by *sff*, or *sforzato assai*.

SHAD (*Alausa* or *Alosa*), a genus of fishes of the family *Clupeidæ*, differing from *Clupea* (the Herring, &c.) in having the upper jaw deeply notched. The teeth are very small, on the jaws only, and often wanting, at least in the adult fish. The species are numerous, inhabiting the sea, but some of them ascending rivers like the salmon, and spawning there. They are very like herrings in form and appearance, and on this account, and their large size, the British species receive from Scottish fishermen the name of *King of the Herrings*.—The COMMON S., or ALLICE S. (*A. communis*), is rather thicker and deeper in proportion to its length than the herring. It is found on the British coasts, and in the lower part of some of the large rivers. It attains a length of two, or even three feet, and a weight of from four to eight pounds. There is a single black spot behind the gills. Its flesh is of good flavour.—The TWAITE S. (*A. finta*) is more plentiful on the British coasts, and is the common S. of the Thames, but the foul state of the river has now made it of very rare occurrence above London. It is smaller than the Allice S., seldom exceeding 16 inches in length; there are small teeth in both jaws, and a row of dusky spots along each side of the body. The flesh is coarser and less esteemed than that of the Allice S., but much used for food wherever the fish is plentiful. This species spawns later in the year than the last. It abounds in many of the rivers of France, and other parts of Europe.—A species of S., *Alosa tyrannus*, generally weighing about four or five pounds, but sometimes twelve pounds, is very abundant during some months of the year in some of the North American rivers, as the Hudson, Delaware, and Chesapeake Bay, and forms an important source of wealth. It is highly esteemed for food. Great quantities are salted. It ascends the rivers, spawns, and returns early to the sea; the young remain at sea, and do not return to fresh water till old enough to spawn. It is not a native of rivers flowing into the Gulf of Mexico, but has recently been introduced there with success. The Ohio Shad (*Pomolobus chrysochloris*) and the Hickory Shad (*Dorosoma cepedianum*) are inferior as food.

SHA'DDOCK (*Citrus decumanus*; see CITRUS), a tree, which, like the other species of the same genus, is a native of the East Indies, and which has been long cultivated in the south of Europe. It is said to derive its English name from a Captain Shaddock, by whom it was introduced into the West Indies. It is readily distinguished from most of its congeners by its large leaves and broad-winged leaf-stalk; it has very large white flowers, and the fruit is also very large, sometimes weighing 10, or even 14 pounds, roundish, pale yellow; the rind thick, white and spongy within, bitter; the pulp greenish and watery, subacid, and subaromatic. It is a pleasant, cooling fruit, and much used for preserves. The tree is rather more tender than the orange, but with proper care is often made to produce fine fruit in orangeries in Britain.

SHADOW is a portion of space from which light is debarred by the interposition of an opaque body. If the luminous body be too near, or too large to be considered as a mere point, then each atom of the light-giving surface throws its own shadow independent of the others. We have thus in reality a multiplicity of shadows overlapping each other, and forming what in common parlance is 'a' shadow of the opaque body, which is darkest at those places where all the separate shadows overlap each other, and becomes lighter as it gradually falls beyond the limits of more and more of these separate shadows. See PENUMBRA. The depth of a shadow depends from mere force of contrast on the intensity of the light around it; it also depends much on the nearness of the object, as compared with its size, to the surface upon which the shadow is thrown; for the rays of light by their properties of reflection, refraction, and dispersion tend to bend 'round' the opaque object, and the increase of distance between an object and its shadow allows more scope for this action.

SHADWELL, THOMAS, a dramatic writer of some note in his day, though now only remembered as the 'Mac-Flecknoe' of Dryden's satire, was born in 1640 in Norfolk. He was educated for the law, but not finding it a pursuit to his mind, he deserted it, and after an interval of foreign travel, betook himself seriously to literature. His first comedy of *The Sullen Lovers* (1668) had great success, and he continued from year to year to entertain the town with a succession of similar pieces, a complete edition of which was published after his death in 4 vols. 12mo. The immortality which these must have failed to achieve for him, he was fated to attain in a way somewhat less desirable. With Dryden he seems, in the earlier portion of his career, to have been on terms of friendly intimacy; but literary jealousies divided them, and the quondam friend became a favourite butt for the shafts of Dryden's

deathless ridicule. Though his works—hasty and careless as they are—exhibit lively talent and considerable comic force, all that the literary world now knows of S. is that 'Shadwell never deviates into sense.' It might a little console him, under the satire of his enemy, that he succeeded him in the post of poet-laureate, which in 1688 it became necessary for Dryden to resign. He did not long survive to enjoy it, however, as in 1692 he died, it is said of an overdose of laudanum, a drug in which he was wont to indulge himself.

SHA'FIITES, the name of one of the four principal sects of the Sunnites (q. v.), or 'orthodox' Muslims. Its name it received from its founder, Abu Abdallah Mohammed Ibn Idris, called Al-Shafei, from one of his ancestors who descended from Mohammed's grandfather.

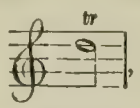
SHAFT, the body of a column, extending between the base and capital. In Gothic architecture, the term is applied to the small columns clustered round piers, or in the jambs of doors and windows. In the early styles, the shafts are frequently of finer material than the pier, such as Purbeck marble, and polished and banded. In later examples, the shaft is generally attached, and of the same piece as the pier. For illustration, see COLUMN.

SHA'FTESBURY, commonly called SHASTON, a very ancient town of England, a municipal and parliamentary borough in Dorsetshire, 27 miles north-north-east of Dorchester. It stands on the narrow ridge of a chalk hill, and commands extensive and beautiful views of the counties of Dorset, Somerset, and Wilts. The date of its foundation is unknown, but it seems to have been a Roman station. In the reign of Athelstan (924—940) it contained two mints and an abbey of Benedictine nuns. Here Canute the Great died in 1036. Pop. (1861) of municipal borough, 2497.

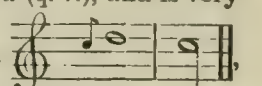
SHAFTESBURY, ANTHONY ASHLEY COOPER, EARL OF, English statesman and philanthropist, is descended from a family intimately associated with the political history and literature of England. Sir John Cooper of Rockbourne, Hampshire, married Anne, daughter and sole heiress of Sir Anthony Ashley of Wimborne, St Giles, Dorsetshire, secretary-at-war in the reign of Queen Elizabeth. Their eldest son, Sir Anthony Ashley Cooper (born 1621), was actively engaged in public affairs during the civil wars. He first espoused the cause of royalty; he then became one of the most eminent of the Parliamentary leaders in the council, and not the least active in the field. When he saw that the restoration was inevitable, he took so prominent a part in bringing back Charles II. that he was raised to the peerage as Baron Ashley. He was a member of the justly infamous 'Cabal' Ministry, and was afterwards appointed to be Lord Chancellor, with the earldom of Shaftesbury. He was the Achitophel of Dryden, by whom his character is drawn with as much truth as power. He hated a calm, lived all his life in intrigues, and in his 62d year his 'fiery soul' wore out his small and fragile body. He will be honoured for all time by men of English race and descent as the author of the Habeas Corpus Act. He also first introduced a bill rendering the judges independent of the crown.—His grandson, ANTHONY COOPER, third earl (born 1671, died 1713), author of the *Characteristics*, the friend of Pope, and the other celebrities of the Augustan age, obtained from Voltaire the questionable praise of being the boldest of the English philosophers.—The sixth earl was for many years Chairman of Committees of the House of Lords.

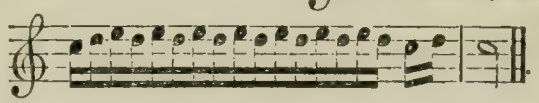
His son, ANTONY ASHLEY COOPER, seventh earl of S., was born in Grosvenor Square, London, April 28, 1801. He was sent to Harrow, and thence to Christ-Church, Oxford, where he obtained a first-class degree in classics in 1822. He represented the borough of Woodstock from 1826 to 1830; the county of Dorset (in which the family estates are situated), from 1831 to 1846; and the city of Bath from 1847 to 1851, when he succeeded to the earldom. During his long career in the Lower House, he held one or two subordinate posts. He is better known by his attempts to improve the social condition of the labouring classes. As he belonged to the Conservative party, and represented an agricultural county, the manufacturers, and their organs in the press, received his allegations respecting the condition of their operatives in a hostile and antagonistic spirit, and retorted that the wages of families engaged in factories amounted to twice and three times the sum paid to the Dorsetshire labourers. Yet Lord Ashley returned again and again to the charge; and on the death of Mr Sadler, M.P., took charge of the Ten Hours' Bill. The manufacturers declared with alarm that any reduction in the hours of labour would be fatal to our manufacturing supremacy. Successive governments naturally believed these prophecies, and almost all the leading statesmen of the day opposed the Ten Hours' Bill. But public opinion declared in favour of a limitation of the hours of labour. Lord Ashley carried his bill through parliament, and has the satisfaction of knowing that the opponents of the measure admit, without an exception, that it was an act of wise and beneficent legislation, and that their alarms were groundless. When he visited the manufacturing districts, he was honoured with an enthusiastic ovation. He refused to join Sir R. Peel's administration in 1841, because that statesman refused to countenance the Ten Hours' Bill. In 1846, he supported Sir R. Peel in his proposal to repeal the Corn Laws, an act which cost him his seat for Dorsetshire. When he successfully contested Bath against Mr Roebuck in 1847, he appeared on the field of politics as a 'Liberal Conservative.' After his accession to the earldom, S. took a more prominent part in connection with various religious, social, and philanthropic societies. These are so numerous that a list of the associations with which he is in some way officially concerned, would include almost every scheme having for its object the physical, moral, and spiritual improvement of society. He belongs to the Evangelical party in the Church of England, and is a prominent member of the chief church societies. He is married to a daughter of the fifth Earl Cowper, and being thus a connection by marriage of the late Viscount Palmerston (whose government he steadily supported), many of the ecclesiastical appointments and promotions of Evangelical clergymen made by that minister were attributed to his influence. He has followed up the Ten Hours' Bill by obtaining the assent of parliament to other measures regulating defective workshops and factories, night work, and the treatment of children by their employers in trades and manufactures. His labours have been powerfully seconded by oratorical gifts of no mean excellence.

SHAG. See CORMORANT.



SHAGREE'N is generally understood to mean shark skin dressed and rubbed down smooth or not; but the Oriental shagreen, formerly in so much repute, consists of portions of the skins of horses, asses, camels, and oxen, the part used being strips taken from head to tail along the centre of the back. These strips are prepared by soaking in water and currying; and when in the proper





condition, they are laid on the ground, and the seeds of *Chenopodium album* are sprinkled over them; a board or piece of felt is then placed on the seeds, and by pressure the hard seeds are forced deeply into the skin, which is then hung to dry. When dry, the seeds are removed by shaking, and the skin pared down with a proper knife nearly, but not quite as low, as the bottom of the depressions caused by the seeds. After this the skin is again soaked, and the parts compressed by the seeds now rise up and form elevations, which are increased by washing in a solution of salt. The last operation is dyeing them of various colours, green being the favourite one. Owing to the difference of texture produced by the operations of compressing by the seeds, paring, &c., the colour is taken irregularly; and when dyed green, the material somewhat resembles malachite in appearance when dried and polished. It was at one time a very favourite material in Britain for covering small cases and caskets of various kinds, especially spectacle-cases.

SHAH (Persian, *prince*, *king*), the general title of the supreme ruler in Persia, Afghanistan, and other countries of Southern and Central Asia. The sovereign, however, may, and frequently does, decline the title, assuming in its place that of *Khan* (q. v.), an inferior and more common appellation. The same title can also be assumed by any of the shah's sons, and upon all the princes of the blood the cognomen *Shah-zadeh* is bestowed.

SHAH-JEHAN, or 'King of the World,' the title assumed on his accession to the throne by Khorrum Shah, the third son of Selim Jehan-Ghir, and the fifth of the Mogul emperors of Delhi. He was during his father's reign employed in military expeditions against the Rajputs, the independent Mohammedan states of the Deccan, and the Afghan tribes around Candahar, in which he greatly distinguished himself by bravery and military skill; but on his return, he was forced into rebellion (1623) by the intrigues of his enemies at court, and was still unreconciled to his father at the latter's death in 1627, when he was at once saluted as emperor by the nobles. At his accession, the empire had reached the summit of its greatness, but the causes which led to its rapid decline at the same time unmistakably shewed themselves: the territory was too extensive for the system of government which was generally pursued by the Moguls; the discordant parts were unconnected by any bond of union; the supreme ruler was looked upon in many provinces as a mere tax-collector; and with the thus necessary absence of any spirit of loyalty, insurrections were frequent in all the provinces. The chief events of S.-J.'s reign were—the war against the Deccan sovereignties, which resulted in the complete destruction of the kingdom of Ahmednuggur (1631), and the subjugation (1636) of those of Beejapur and Golconda; an indecisive contest against the Uzbeks of Balkh (1644—1647); two unsuccessful attempts to recover Candahar from the Persians; and a second successful war, conducted by his third son, Aurungzebe, against the Deccan princes (1655). But in 1657 the emperor fell dangerously ill, and his four sons, who were ambitious of attaining supreme power, immediately commenced to dispute regarding the succession. See AURUNGZEBE. Ultimately, S.-J. was taken prisoner, and confined in the citadel of Agra till his death, December 1666. S.-J. united the voluptuous profligacy so common in Eastern monarchs with great sagacity, and the strict administration of justice to Moslem and Hindu alike. In his later years he became avaricious, increased the taxes, and confiscated the property of his wealthier subjects on the slightest pretexts. The magnificence of his court was unequalled; the splendid 'peacock-throne' was constructed by his orders at a cost of about £7,000,000, and many magnificent public buildings executed under his direction remain as monuments of his greatness. Chief of these are the city of Shahjehanabad, and the superb mausoleum of Tajmahal (q. v.). Yet so strict was his financial management, that he left a well-appointed army of 200,000, and a treasury containing £24,000,000 to his son Aurungzebe.

SHAH NAMEH, Book of Kings, the title of several Eastern works, the most celebrated of which is the Persian poem of this name by Firdusi (q. v.), containing the history of the ancient Persian kings in about 60,000 distichs, and written by the order of Sultan Mahmud of Ghizni, in the space of thirty years. Another work, in Turkish, under the same name, comprises the history of all the ancient kings of the East, and was written by Firdusi Al-Thauil. Bajazet II., to whom the book was dedicated, ordered the author to reduce it from its original bulk of 300 volumes to 80. Firdusi, however, felt so mortified at this proposal, that he preferred leaving the country altogether, and emigrated to Khorassan, in Persia.

SHAKE, in Music, an embellishment produced by the continued and rapid repetition of one note alternately with another either a whole tone or semitone above it. Its sign is *tr* (the first two letters of the Italian *trillo*), placed over or under the principal note. For example: 

, is played thus:  ; the exact number of repetitions being indefinite. A shake is often preceded by an Appogiatura (q. v.), and is very generally finished with a turn, as  , played:  . We may have shakes on two notes at once; and a series of shakes on several notes is called a chain of shakes.

SHAKSPEARE, WILLIAM, the chief literary glory of England, was born at Stratford-on-Avon, in Warwickshire, it is believed, 23d April 1564. Certain it is, as vouched by the parish register, that his baptism took place three days after, on the 2 th. His father, John Shakspeare, seems to have belonged by birth to the class of yeomen. His mother, Mary Arden, was of more distinguished origin. She came of a good old Warwickshire family; and when married, she brought to her husband as dower a property called Asbies, 54 acres in extent, besides an interest in certain other lands at Wilmecote, and a small sum of money. In a contemporary document, John Shakspeare is described as a *glover;* and this trade, at that time a more important one than it has since become, there is evidence to shew that he conjoined with that of a farmer and rearer of stock. His earlier career was one of steady prosperity, and the consideration in which he came to be held as a citizen, is shewn in the fact of his having, in 1569, been elected chief magistrate of Stratford. Of a family of four sons and four daughters born to him, William was the third child. At the free grammar-school of Stratford there can be little doubt the young S. received his entire

education. As to the precise character and amount of this, there has been much controversial conjecture; some writers maintaining, on the internal evidence of his works, that he must have enjoyed a thorough classical training, whilst others represent him as probably destitute of any such youthful advantage. The celebrated 'And though thou hadst small Latin and less Greek' of his friend Ben Jonson, which has been frequently quoted as certifying his almost utter ignorance, seems, if anything, to tell the other way. It assures us that, of both languages, he knew something; as to *how much* of either he may have known, it affords us scarce a ray of light, inasmuch as it is impossible for us even to guess at the amount of classical attainment sufficient, in the eyes of a scholar, and something of a pedant, like Jonson, to entitle a man to the praise of having *much* Latin and Greek. What Ben might contemptuously style 'small Latin' was, in all probability, as it seems to us, a fair working allowance of it.

Meantime, misfortune had overtaken, and more and more come to press heavily on John Shakspeare; in consequence of which, William, now somewhat over fourteen, was withdrawn from school, and set to do something for his living. How he was employed from this time till his departure for London, it is impossible to make out with distinctness. One tradition informs us that, for a time, he served as apprentice to a butcher; and it is said that, 'when he killed a calf,' the poetry of his nature prompted him to ennoble the operation as he could to himself, by 'doing it in a high style, and making a speech.' Unhappily, none of his speeches have come down to us, so that rather more of a mythical atmosphere than might be wished surrounds this pursuit of the ideal under difficulties. But that he was for some time a butcher's assistant, is as likely to be true as not. Another story has it, that for some years he was a schoolmaster; whether or not in birching his boys he dignified the act as in the calf's case, tradition has omitted to inform us. Both stories are not unlikely to be true; the fact of the matter probably was, that in those years young S. lived miscellaneously as he could. Out of the cloud of uncertainty which shrouds this period of his life, two facts, however, emerge as beyond question—his marriage, and the birth of his eldest born. As soon as may be after the 28th November 1582—on which day the licence was procured at Worcester—Shakspeare, a lively lad going nineteen, was married to Anne Hathaway of Shottery, a hamlet some mile or so out of Stratford, a damsel about eight years older than himself; and six months afterwards a daughter was born to him, whose baptism bears record 26th May 1583. The obvious inference from this promptitude on the part of his spouse certain of his admirers have sought to evade. It is said, and we believe it is certain, that a mere betrothal before witnesses, to be followed within some reasonable undefined period by the religious ceremony, was then and there held to constitute a valid marriage; and this, it is conjectured, may in S.'s case have prefaced the more formal sanction. And of course it may; the licence of conjecture is unlimited; and all to whose comfort in admiring a great genius it is essential to regard him at every point of his career as also a pattern of everything that is proper, must of course be made welcome to this one. The only other children born of the marriage were twins, a boy and a girl, baptised 2d February 1585. The boy (Hamnet) did not survive his father, dying in his twelfth year.

As nearly as can be made out, in the year 1586, S., then 22, left the neighbourhood of Stratford, and betook himself to London. A local tradition assigns as his reason for doing so a mishap which befel him, and a little imprudence consequent on it. The future poet, it is said, while out on a nocturnal poaching expedition in the deer-park of a neighbouring magnate, Sir Thomas Lucy of Charlecote, was caught by the keepers, kept for the night a prisoner, and arraigned before Sir Thomas—a justice of peace—in the morning. What passed is not recorded; but—as the old rumour goes—whatever it was, it excited the ire of S., who avenged himself, as a bard naturally might, by circulating 'a bitter ballad' in which the good knight was satirised. A further prosecution was for this irreverence directed against him, to escape which it was that he is said to have fled to London. No anecdote concerning S. has been more widely accepted than this, or, on the whole, seems better to deserve acceptance. An obvious allusion to the Lucies of Charlecote in the *Merry Wives of Windsor*, which identifies their coat of arms with that of Justice Shallow, would of itself afford strong confirmation of it. Further, Oldys, an antiquary who died in 1761, and had busied himself much about materials for a life of S., certifies the story on something like fair evidence, and gives the first verse of the obnoxious pasquinade, as remembered in the district. It is more coarse and scurrilous than witty; but inasmuch as it would be easy to adduce passages from the admitted writings of S., in which the coarseness to at least an equal extent preponderates over the wit, this will scarcely of itself amount to proof that he could not possibly have been its perpetrator. The indisposition which more lately has been shewn to attach any credit to the tale, seems to rest entirely on a foolish horror of admitting anything as possible in the conduct of the poet which might any way seem to conflict with the reverence now universally accorded to his genius.

No certain details have come down to us as to S.'s earlier relations with the London theatre. According to one tradition, he was content at first to turn a penny by holding horses at the door. According to another—which seems in a natural sequence with the foregoing—we find him admitted inside on his promotion, though as yet only in the humble capacity of prompter's attendant. What is certain in the matter is this, that if at any time he was thus meanly occupied, it could have been only for a brief period, as very speedily we have note of him as a man of some importance, at once dramatist, actor, and shareholder in the Blackfriars Theatre. As an actor—though we find one contemporary allusion to him as 'excellent in the quality he professes'—he seems at no time to have shone especially, being rather respectable than eminent. As dramatist, his magnificent powers were at once recognised, and in no long time had won for him the very foremost rank among the writers for the stage of his time. The extraordinary rapidity of his rise is shewn in this indubitable reference to him in Spenser's *Tears of the Muses*, published so early as 1591, only some five years after S.'s arrival in London:

> And he, the man whom Nature's self had made
> To mock herself, and truth to imitate,
> With kindly counter under mimic shade,
> Our pleasant Willy, ah, is dead of late.

The reference here has indeed been surmised to point at Sir Philip Sidney, by Spenser elsewhere alluded to under the figure of Willy a shepherd; but the surmise is, on various grounds, inadmissible. The first two lines have the closest critical pertinence to the character of S.'s genius; as applied to that of Sidney, they are, by comparison, vague and unmeaning. Further, the 'mimic shade' in the

third line, together with the whole context of the passage, makes it certain a dramatic writer is alluded to; and this Sidney was not. Moreover, the stanza which follows, wherein of 'that same gentle spirit' it is said that he

> Doth rather choose to sit in idle cell,
> Than so himself to mockery to sell,

must needs be held to indicate a man at the time living; and Sidney had died in 1586. The 'Ah, is dead of late!' which, literally taken, would suit Sidney, and not S., must, in the light of the succeeding couplet, be interpreted as referring to some temporary remission on the part of the latter of his wonted dramatic productiveness; and this, if not otherwise to be accounted for, we might explain by supposing him at this time engaged on his two elaborate poems, *Venus and Adonis*, and *The Rape of Lucrece*, published not long afterwards. The year after (1592), we find a contemporary and brother dramatist, Henry Chettle, making the *amende* to S. for an offence given, in terms most respectfully appreciatory of his excellences at once as a man and an author; and in 1598, Francis Meres, in his *Wit's Treasury*, writes of him as admittedly the 'most excellent among the English for both kinds of tragedy and comedy.' We have ample evidence besides of the unrivalled acceptance his works obtained from all classes; not only were they in the wider sense popular, but they brought him special marks of favour and approval from Queen Elizabeth and her successor, James—who is said to have honoured the poet with an 'amicable letter' from his own hand—and procured him the patronage and friendship of some of the most accomplished men of rank of the time, more notably, Henry Wriothesley, Earl of Southampton, to whom he dedicated his *Venus and Adonis*, and *Rape of Lucrece;* and William Herbert, Earl of Pembroke, commonly held to be the 'Mr W. H.,' to whom, as their 'only begetter,' his *Sonnets* are addressed.

S. was plainly—as men of *consummate* genius mostly are—a man of shrewd solid business ability; and throughout, his material prosperity kept pace with the growth of his poetical reputation. He became early, as we saw, a considerable shareholder in the Blackfriars Theatre. In the Globe, subsequently erected, he was also a part proprietor. To both he contributed dramas, and from his gains in the triple capacity of actor, author, and sharer of the general profits, he rapidly amassed a fortune. His local attachments were strong, and it seems to have become, as his wealth increased, one main object of his ambition to settle himself as a substantial country gentleman in his native district, to which annually he made a visit. We find him, with this view, from time to time making purchases there of house and landed property. By and by, his visits to Stratford became more and more frequent; and it is positively certain that previous to the year 1613, he had ceased to reside in London, and finally established himself at Stratford. Of his last years there spent, further than that they lapsed peacefully in honour, and the exercise of a liberal and kindly hospitality, nearly nothing is known. There is evidence of his having more or less occupied himself in agricultural pursuits, and good reason to believe that, though withdrawn from other active concernment with the stage, he still continued to write for it. His death took place on his 53d birthday, the 23d April 1616. In the diary of a Mr Ward, the vicar of Stratford, writing *apud* 1660, the cause of it is thus given: 'Shakspeare, Drayton, and Ben Jonson had a merry meeting, and, it seems, drank too hard, for Shakspeare died of a fever then contracted;' but that of this drinking the poet's death was a consequence is at best a doubtful inference.

That S. erred and sinned at times like others, we know from the passionate confessions of his *Sonnets*, in considerable portions of which the self-reference is too plain to be denied; but that, whatever his occasional frailties, he was essentially a man of noble and estimable character, there is a complete concurrence of testimony. He was obviously of most kindly and lovable dispositions; his 'pleasurable wit and good nature' made him delightful as a companion; and it was as 'gentle Will Shakspeare' that he was familiarly known to his contemporaries. In particular, with his associates and rivals in writing for the stage, his relations would seem to have been of the most cordial and even endearing kind. The gruff Ben Jonson writes of him after his death: 'He was honest, and of an open and free nature,' assures us that in 'his well-turned and true-filed lines' we see but an authentic reflex of his beautiful 'mind and manners;' and avers that he 'honours his memory only on this side idolatry.' As a slight shadow on this pleasing picture, it has been shrewdly surmised that he was not very happy with his wife. Evidence of this has been sought in certain passages in his dramas; but obviously any inference from these is most precarious. The neglect of her in his will, except in one curt clause interlined, dismissing her with a legacy of 'his second-best bed,' might well seem much more decisive, till Mr Charles Knight greatly reduced its importance by shewing that, the will apart, by the mere operation of the English law, the poet's widow was entitled to *dower*, and thus amply provided for. There is thus (though the query of why *second*-best, if a bed at all was to be left her, may perhaps have a certain pertinence) no very firm basis of proof for the domestic unhappiness of Shakspeare. Still, if anything in his life is certain, it is this, that, spending great part of his time in London, the poet did not find it essential to his felicity there to have the society of his wife; as probably she, on the other hand, though her husband had gone to the metropolis, was content to abide in Stratford, since it seemed to him the desirable arrangement. It is fair, we think, to infer from this that the affection subsisting between the two was a little on the hither side of enthusiasm.

To discourse here at this date of the genius of S. would be only to promulgate platitudes. The lofty eulogy of Dryden—'He was the man who, of all modern and perhaps ancient poets, had the largest and most comprehensive soul'—has since been generally acquiesced in. As dramatist, he is admittedly in the world without a peer; as poet (abstracting the differential forms), there are but one or two names in literature even to be named beside his; and dismissing his claims in either kind, we have in his works such a treasury of gnomic wisdom on all matters of human concernment as no other writer has ever bequeathed to the world. If we add, that this greatest of writers is one of the most unequal—that his works contain more than might be wished of what, as the product of such a mind, we need not scruple to call rubbish—and that nearly every vice in writing might be illustrated from them almost at will, we say simply what is patent to every reader not blinded by the stupid and mindless idolatry which too often of late in many quarters has displaced a rational admiration.

The only works of S. certainly published under his own hand were the two poems *Venus and Adonis* and *The Rape of Lucrece*, which appeared in 1593—1594 respectively. As was naturally to be looked

for in the case of pieces on the stage so popular, certain of his dramas found their way from time to time into print, but no authoritative edition of any of them was issued during his lifetime. The first collected edition of his dramas was issued in 1623, by Heminge and Condell, his friends and co-proprietors in the Blackfriars and Globe theatres. A second edition followed in 1632; a third, in 1664; and a fourth in 1685. In 1709, appeared the edition of Rowe, with a prefatory sketch of the poet's life. Of the 'Shakspearian literature' which followed, and the various re-issues of the dramas, with such masses of critical commentary and emendation as no other writer has ever perhaps been made the subject of, it would be hopeless to attempt an account. It must suffice to mention as successive editors Pope, Theobald, Sir Thomas Hanmer, Warburton, Capell, Stevens, Malone, and Dr Johnson, whose elaborate introductory essay—whatever may be thought of the insolence of much of his criticism of the plays in detail—is perhaps on the whole, as an estimate of the genius of the poet, as satisfactory as any that has since been written. Down to our own time, there has been no remission of activity in this field of literary labour. More recently, the intelligent industry of Mr Charles Knight specially deserves mention; and along with his may be given the names of Mr Dyce, Mr John Payne Collier, and Mr Singer—all of whom have put forth elaborate and valuable editions of the dramas. In 1864—1865 an important edition (the Globe) was issued from Cambridge (Eng.), Boston, and Philada., under the superintendence of those competent scholars, W.G. Clark and W. A. Wright, with a glossary by Rev. J. M. Jephson.

In Germany, S. has long been thoroughly naturalised; and the German enthusiasm in regard of him is, if possible, even greater than our own. It was the celebrated Lessing who first decisively introduced him to notice in a series of essays, exhibiting the immeasurable superiority of his art to that of the pseudo-classical models of the French stage. Since his time, many of the most gifted of his countrymen have devoted themselves to the work of Shakspearian criticism and elucidation. From Goethe we have some exquisite fragments, most notably the criticism of *Hamlet*, occurring in his *Wilhelm Meister*; and after his, the names of Tieck, A. W. Schlegel (whose *Lectures*, of date 1809—1811, almost constitute an era in this special department of literature), Franz Horn, and Gervinus (an English translation of whose elaborate Commentaries has been published), occur as the most illustrious in connection with the present topic. By Tieck and Schlegel together, the work of translation was undertaken; and the result of their joint labours, which takes rank as the standard German S., ranks also, in the opinion of competent judges, as a consummate and almost *unique* specimen of excellence in the translator's art. It has not unfrequently been alleged that, till the Germans made the discovery for them, the English people knew nothing of the greatness of Shakspeare. This is on the face of it ridiculous. The single sentence we have cited from Dryden, and the practical acceptance of it implied in the unexampled attention and industry which never ceased to be directed to the subject, sufficiently of themselves confute so idle a notion. What the Germans really did (and along with their services in the matter, must be included those of our countryman Coleridge, whose impulse and point of view, at least, if not something considerably more, were derived from German sources) was somewhat to methodise and enlighten for us an admiration never deficient, but always, like Jonson's regard for the memory of his friend, 'only on this side idolatry.' The old notion of S. was that of a genius in power and plenitude unrivalled, but licentious in its modes of operation, and more or less chaotic in its results; 'wild above rule or *art*, enormous bliss.' The new German criticism exhibited in the chaos the orderly outlines of a world; co-ordinated the confusion under rules till then unsuspected, and shewed in what before had seemed irregular exercise of power admitted to be magnificent, obedience not less magnificent to a law of artistic evolution. It made calculable, in a word, the orbit of a luminary which had somewhat uncomfortably seemed to be sweeping at random through space. But the English people did not need it to *reveal* the luminary to them; throughout and from the first, they had seen and devoutly worshipped it. Also, to a great extent, it is due to the German enthusiasm of exposition, that over the whole continent, and wherever literature is intelligently studied—some little lingering, dying remnant of French prejudice excepted—the poet *par excellence* of England is now finally enthroned as the poet also *par excellence* of our whole modern world and civilisation. For numerous critical notices, list of editions, and Shakspeareana, see a remarkable article in Allibone's *Critical Dictionary of English Literature* (Philada., 1871).

SHALE, or SLATE-CLAY, an indurated clay, which often forms beds in the coal measures. It is chiefly composed of silica and alumina, in variable proportions, but also frequently contains a considerable amount of carbonate of lime and of oxide of iron. It is of a gray or grayish-black colour, or brownish-red when containing much iron. Its structure is more or less slaty. It is soft, and easily reduced to powder. It is used for making slate-pencils. When free from lime and iron, it is reduced to powder, and used for making fire-bricks, for which it affords an excellent material. S. very often contains a notable quantity of bitumen, and when this is so much the case that the mineral has a shining resinous streak, and crackles and blazes in the fire, emitting a black smoke and a bituminous odour, it is known as *Bituminous Shale*. This variety sometimes passes on the one hand into common S., and on the other into coal. Impressions of ferns and other plants are very frequently found in shale.

Slate, Schist, and Shale are names employed to denote those kinds of rock which are laminated or fissile—that is, which possess a structure readily splitting into thin layers. Shale and schist are almost synonymous, although the latter should be restricted to rocks with their layers irregular or foliated. True slate differs from them in not having its lamination produced by bedding. See SLATE. Nevertheless, all three names are often applied to the same substance.

Shale varies much in its composition. Clay, sand, lime, bitumen, and other bodies, either singly or any mixture of them, are included under the name, if they form rocks which split into layers in the direction of their bedding; clay, however, being an ingredient in most shales. Strange as it may seem, the line between even coal and some kinds of shale is not well defined; and in the case of the Torbanehill mineral, found near Bathgate, the question by which of the two names it should be called, led to a lengthened and costly litigation.

The importance of certain decomposing shales, through which sulphuret of iron is disseminated, for the manufacture of alum, has been long known, and the quantity raised for that purpose from the carboniferous beds of Lancashire and Lanarkshire and the lias beds of Yorkshire is very considerable, yielding about 16,000 tons of manufactured alum annually. Shales of a similar kind are worked in France, Germany, and North America.

Bituminous shales—that is, shales more or less

rich in carbon and hydrogen—form another class of those bodies which have, in recent years, attracted much notice as sources of oil for illuminating purposes. It is now (1871) more than twenty-five years since a Frenchman, named Du Buisson, introduced a method of distilling certain bituminous shales in France, at a comparatively low temperature, so as to obtain burning oil and other products. The process was afterwards tried in England, being used for a time in distilling a Dorsetshire bituminous shale, sometimes called 'Kimmeridge coal.' From this mineral, a burning oil, a lubricating oil, and a naphtha for dissolving caoutchouc, were obtained. But neither in France nor in England did the attempt to make a profitable manufacture succeed: in the former country, the poverty of the shales was the chief drawback; in the latter, the disagreeable smell of the oil, which could not be effectually removed, prevented it from obtaining favour in the market.

On account of these failures, the process fell into abeyance, until it was revived again by the success of the well-known patent of Mr James Young (see NAPHTHA), secured in 1850 for the production of paraffin and paraffin oil from coal. With the exception of the solid paraffin, which Mr Young was the first to obtain on the large scale, and the employment of coal instead of shale, the processes of Du Buisson and Young are essentially the same. The merit of this process is very great, because not only has it created a new and rapidly-increasing branch of industry, in the case of the distillation of paraffin oils from coal, but it has within these few years been applied again, and with great success, to the obtaining of the same products from shale. Those who have paid any attention to the various beds of minerals which go to form what is geologically called the Coal Measures, are aware that it is only the seams of coal, ironstone, fire-clay, sandstone, and limestone, which until very lately have been looked upon as of any industrial importance. Interstratified between these and the other minerals of the series, are numerous hitherto uncared-for beds of carbonaceous or bituminous shale. Many of these shales were found upon trial to yield from 30 to 50 gallons of crude oil per ton; and works—several of them of great size—have accordingly been started in many places over the entire area of the coal formation in Scotland, and also at various localities in England and Wales, for the manufacture of paraffin and paraffin oil from this material. These products, moreover, happen to be obtained with greater facility in a pure state from shale than from coal, so that it is not unlikely the use of coal, as a source of them, will sooner or later be abandoned. Some of the lias shales have likewise been profitably distilled for oil, as well as those of the carboniferous age; and it is thought highly probable that several of the older Silurian and Old Red Sandstone shales may also prove valuable for this purpose. Quite recently, a shale, very rich in oil, has been sent from a country so distant as Brazil for trial in England. It happens that in the manufacture of paraffin oil from coal or shale a good deal of coal-gas is unavoidably produced and wasted; and proposals have already been made to convey this from various large oil-works for consumption in towns. In these days of the wondrous utilisation of waste materials, the obtaining of an illuminating gas as a collateral product of the manufacture of mineral oil, will probably prove before long to be not the least curious.

SHALLOO'N, a light worsted cloth, said to have been first made at Chalons in France, and to have derived its now corrupted name from that place.

SHA'LLOP (Fr. *chaloupe*), a large, open, old-fashioned boat, carrying two masts, rigged as in a schooner. Its principal use was in the fisheries, but it has now nearly given place to luggers and yawls.

SHA'LLOT (*Allium Ascalonicum*), a species of *Allium* (q. v.), a native of the East, introduced into Europe by the Crusaders—from Ascalon, it is said—and much cultivated for its bulbs, which are used like those of the onion, and sometimes for its leaves, which are used like those of the chive. The leaves grow in tufts like those of the chive, but are larger. The S. is generally propagated by the cloves, which are planted just beneath the surface of the ground, or only partially beneath it, in spring, and the crop is ready for gathering in July or August. The flavour resembles that of garlic, but is much milder. In the vineyards of Italy the S. is naturalised.

SHA'MANISM is the ancient religion of the Tartar, and some of the other Asiatic, tribes. It is a belief in sorcery, and a propitiation of evil demons by sacrifices and frantic gestures. The following account of it is extracted from the *Asiatic Journal*. The priests are men or women, married or single. The character is acquired by pretending that the soul of a deceased priest has appeared to the individual in a dream, appointing him or her his successor. If the priests are in function, they wear a long robe of elk-skin, hung with small and large brass and iron bells; moreover, they carry staves carved at the top into the shape of horses' heads, also hung with bells; and with the assistance of these staves, they leap to an extraordinary height. The followers of the Shaman religion have neither altars nor idols, but perform their sacrifices in a hut raised on an open space in a forest or on a hill. Nor are there fixed periods for the performance of their ceremonies; births, marriages, and sickness, uncommon appearances in the atmosphere, or public calamities, are generally the occasions which call for them. The animal to be sacrificed is generally fixed upon by the Shaman or the donor; and after the persons uniting in the ceremony have assembled, the Shaman enters the hut, chanting certain words, sprinkles on all the sides of the hut, and over the fire, spirits and milk, and then orders the animal to be killed, which is done by its heart being torn out. The skin of the victim is then stripped off, and its flesh, with the exception of a few pieces which are thrown into the fire, is consumed by the persons assembled. See also LAMAISM.

SHAMMAI (not, as has often been done, to be confounded with Sammeas), an eminent doctor of the Jewish law at the time of Herod, head of a most important school, and supreme judge of the Sanhedrim (Ab-Beth-Din) during the presidency of Hillel (q. v.), along with whom he is, indeed, generally mentioned, and of whom he was, as it were, the very counterpart. Very little is known of the history of his life. He most probably was born in Palestine, and most energetically participated in all the political and religious complications of the country. There was a harshness and rigidity in his character, which contrasts most strikingly with Hillel's proverbial patience. His religious views were painfully strict, and he even tried to extend the rigour which he imposed upon himself, to the youngest children; but the zealotism with which later times have charged him, is not his, but his school's, 'the House of Shammai,' as it was called. This seems, under the adverse circumstances of the commonwealth—sedition within, and the approaching enemy without—to have developed a fanatical zeal that at times surpassed all bounds,

and chiefly tended to foster that exceptional exclusiveness which proved both the bane and the saving of Judaism. The discussions of the two rival schools, of which that of S. preponderated long after the master's death, turned exclusively upon points of positive law. There is only one curious metaphysical debate recorded, viz., whether, as one school held, 'it was better for man to have been created or not;' or, as the other asserted, 'it would have been better if he never had been created.' Finally, they both agreed in the latter axiom, but with the addition—'but since he is now in this world, let him be careful in his actions.' We need hardly point to the strange light which this discussion and final decision throw upon the times of unequalled national misery that begot them.

SHA'MMOY. See LEATHER.

SHA'MO, SHA-MOH, or GOBI, words signifying Sandy Sea or Desert. Geographers divide the region so called into an eastern and western portion. The eastern part of this great desert stretches from the eastern declivity of the Thian-Shan Mountains in long. 96° to 120° E., and about lat. 40 N., as far as the Inner Hing-an; and its width between the Altai and the In-shan range varies from 500 to 700 miles. Through the middle of this tract extends the depressed valley, to which more properly the term 'Sandy Floats' is particularly applicable; it is from 150 to 200 miles across, its lowest depression being from 2600 to 3000 feet above the sea. Sand almost entirely covers the surface of this valley, generally level, but sometimes rising into low hills. Such vegetation as occurs is scanty and stunted, affording indifferent pasture, and the water in the numerous streamlets is brackish and unpalatable. The western portion of this desert, lying east of the Tsung Ling, and north of the Koulkoun, between long. 72°—96° E., and in lat. 36°—37° N., is about 1200 miles in length, and between 300 and 400 across. This region is an unmitigated waste, and north of Koko-nor assumes its most terrific appearance, being covered with dazzling stones, and rendered insufferably hot by the reflection of the sun's rays from these and numerous mountains of sand, which are said to move like waves of the sea. The limits of the western portion of the desert are not easily defined, for near the base of the mountain-ranges, streams and vegetation are usually found. The entire area of S. is about 1,200,000 sq. miles. The general features of this portion of the earth's surface are less forbidding than Sahara, but more so than the steppes of Siberia, or the pampas of Buenos Ayres.—Williams's *Middle Kingdom;* Huc's *Travels.*

SHA'MROCK, a national emblem of Ireland, a leaf with three leaflets, or plant having such leaves, sometimes supposed to be the Wood Sorrel, but more generally believed to be some species of Clover, or perhaps some common plant of some of the nearly allied genera, as the Bird's Foot Trefoil, or the Black Medick. It is not improbable that the name has a sort of general reference to plants with trifoliolate leaves, and that a more exact determination of the species may be as difficult as the attainment of botanical accuracy in regard to the emblematic thistle of Scotland.

The small-leaved clover (*Trifolium repens*) has had a superstitious respect attached to it from early times. According to the elder Pliny, no serpent will touch it. It is said to have been first assumed as the badge of Ireland, from the circumstance that St Patrick made use of it to illustrate the doctrine of the Trinity. See TREFOIL.

SHAMYL, or SCHAMYL (Eng. 'Samuel'), the celebrated leader of the independent tribes in the Caucasus, was born at Aul-Himry, in Northern Daghestan, and belonged to a wealthy Lesghian family of rank. He was one of the zealous disciples of Kasi-Mollah, the great apostle of Muridism, and ably seconded his endeavours to compose the numerous feuds of the various Caucasian tribes, and unite them in a bond of antagonism to their common enemy, the heretical Russians. He was one of the foremost in the defence of Himry against the Russians, October 30, 1832, and after the fall of his chief, Kasi-Mollah, and most of his adherents, fought his way alone and severely wounded through the besiegers' ranks. After the assassination of Hamzad-Bey, the successor of Kasi-Mollah, in the end of 1834, S. was unanimously elected 'imaum,' and being absolute temporal and spiritual chief of the tribes who acknowledged his authority, he made numerous changes in the religious creed and political administration, for the purpose of more fully concentrating in himself the whole power. These changes were certainly the chief cause of the great successes which subsequently attended the mountaineers, but it is none the less certain that they produced that sudden collapse of the spirit of independence which took place when the great leader was removed. S.'s change of military tactics, from open warfare to surprises, ambuscades, &c., brought numerous, and sometimes great successes to the arms of the mountaineers. General Ivelitch was severely defeated in 1837, the worst reverse the Russians had yet sustained, and his coadjutor Hafi was forced to make a disastrous retreat. They succeeded, however (1839), in hemming S. into Akulgo, in Daghestan, took the fortress by storm, and put every one of the defenders to the sword, in order to be quite certain that S. should not escape. How he did so is not known, his own followers and the Russians believed him to be dead, when, to the joy of the one and the bitter confusion of the other, he suddenly appeared, preaching with more vigour than ever the 'holy war against the heretics.' In 1843, he conquered all Avares, besieged Mozdok, foiled the Russians in their subsequent campaign, and gained over to his side the Caucasian tribes which had hitherto favoured Russia. This accession of power rendered necessary some change in the government; a civil and a criminal code were promulgated, a regular system of taxation established, and Dargo was made the capital of this Caucasian monarchy, the population of which now (1844) exceeded 1.000,000. But the Russians, under Prince Woronzoff, having changed their tactics, assailed the country on various points at the same time, and the advance gained was secured by chains of forts. The fortune of war, however, steadily alternated till 1852, when Bariatinsky compelled S. to confine himself to the defensive, and deprived him of his victorious prestige. Some of the tribes now returned under Russian authority, and S. (probably owing to his diminished power and resources) was unable to take advantage of the diversion in his favour afforded by the Crimean War; after the conclusion of which the Russians resumed their attacks with more energy, opened a road over the mountains, thus cutting off one portion of the patriots, and compelling their submission. The following year was still more disastrous; 100 villages were destroyed, the inhabitants transplanted to Russian districts, and S. himself defeated, August 11. On April 12, 1859, his chief stronghold Weden was taken after a seven weeks' siege, and his authority, except over the small band of followers who still devotedly adhered to him, was wholly destroyed. For several months he was a mere guerilla chief, hunted from fastness to fastness, till at last (September 6, 1859) he was surprised on the plateau of

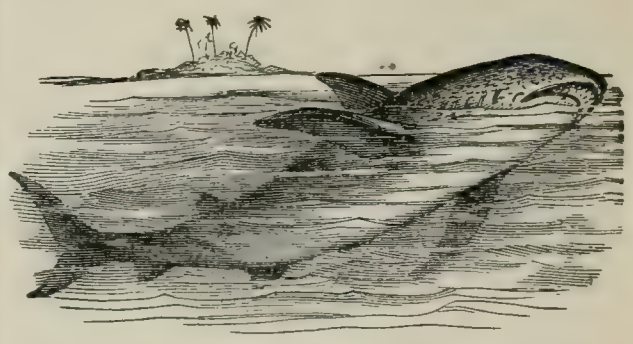
Gounib, and after a desperate resistance, in which his 400 followers were reduced to 47, he was captured. His wives and treasure were spared to him, and he was sent to St Petersburg, where he experienced a generous reception from the czar. A few days afterwards, he was assigned a residence at Kaluga, with a pension of 10,000 roubles. From that time until the date of his death in 1871 he remained in obscurity as a sort of parole prisoner of the Russian government.

SHANGHAI', the most important maritime city of China, situated on the left bank of the Hwang-poo or Woosung River, 12 miles from where it debouches into the southern portion of the mouth of the Yangtse-kiang, in lat. 31° 10′ N., and long. 121° 30′ E. It is a *heen* or *district* city, having a wall 3 miles in circuit, through which 6 gates open into extensive suburbs. The low alluvial plain on which it is situated is of great extent, and intersected by innumerable streamlets and canals, which environ the walls, and permeate the city in various directions. It is a dirty, poorly-built town, the houses are mostly brick, the streets are very narrow, and constantly crowded with people. Few of the buildings rise above the low walls of the city; the only conspicuous objects are the Roman Catholic cathedral, a massive edifice, and the lofty spire of the Baptist chapel. The temples present the same general appearance met with in all Chinese cities. Every city has its Ching-hwang, or temple of the tutelary gods; that of S. is in a picturesque position on a rocky islet, surrounded by a serpentine sheet of water, which is crossed by zigzag bridges. In close juxtaposition to these finest specimens of Chinese taste, is the beautiful foreign settlement that has sprung up on the banks of the river to the east of the city. Merchant princes have reared for themselves, to occupy during a brief residence, edifices that may be justly termed palatial. First, on emerging from the east gate, the native finds himself in the French Reservation, which is gradually being filled up with buildings, forming a city under the jurisdiction of that power. On crossing a canal, he beholds a city apparently as large as his own—the English quarter; streets parallel with, and at right angles to the river, paved and well lighted, bearing English names, and faced with substantial stuccoed brick buildings, ornamented with colonnades, having garden space in front of each filled with choice flowers. He sees, at the rear of this marvellous city which has suddenly sprung up before his eyes, a race-course and a church—two things to be found wherever Englishmen congregate abroad. The river in front of the Chinese town is thronged with junks, lashed side by side for a couple of miles, the reach in front of the foreign settlement being crowded with square-rigged vessels, numbering sometimes above 100. Lower down are the ship-yards, machine-shops, and dry-docks, which foreign commerce has called into existence. Tugs are constantly steaming to and fro, towing ships and junks against the impetuous tides of the Yangtse. Under the arrangement by which the foreign custom-house dues are collected by foreigners, facilities have been created for the navigation by stationing a light-ship, buoys, and signals, rendering safer the approach to this important mart. There is also a system of foreign pilotage, giving additional security to the mariner. There are a chamber of commerce, reading-room, library, and literary institution—nothing being wanting to render the port of S. the metropolis of Eastern commerce. The municipal government of the foreign settlement is highly creditable to the mercantile traders. Three gentlemen, generally two English and one American, are elected annually by the holders of land, for the purposes of local government—police, public improvements, and repairs requiring much management, and entailing much expense, the funds for which are obtained by taxation. S. is also the seat of various missions for converting the natives, the schools, dispensaries, and other benevolent objects meeting with generous support from foreign merchants. The products of S. itself are not of much value, but the city is a most important entrepôt for goods passing between the north and south provinces of China, as well as for the imports and exports from and to foreign countries. The trade of the port increased threefold between the years 1860 and 1863; and this increase is due in a great measure to the large and increasing trade from the ports opened on the Yangtse in Chinese produce of all descriptions. In 1867 the entrances and clearances were 1745 vessels, of 801,537 tons (384 American, of 224,082 tons); and 1734 vessels, of 806,661 tons (378 American, of 221,413 tons). In 1868 the imports amounted to £6,370,918, and the exports to £15,607,757; the tea exports from S., in 1867, to the United States, amounted to 15,978,576 pounds. 40,000 chests of opium were imported into S. in 1867. The chief articles of import are opium and treasure, and of export tea and silk. Great quantities of the opium and treasure imported into S. are re-exported to the other parts of China, to Japan, &c. The mercantile importance of S. promises to increase greatly through the opening of the Yangtse River to commerce. Pop. 1868, 149,475, of whom 2248 are foreigners. See North China (Shanghai) *Herald*, and *Commercial Reports* (1865—1870).

SHA'NNON, the largest of the rivers of Ireland, rises in the Cuilcagh Mountains, county of Cavan, and after a course of 220 miles, falls into the Atlantic Ocean between the headlands of Loop and Kerry Head. It is commonly divided into two portions, the Upper S. from its source to Limerick, and the Lower S. from Limerick to the sea, a distance of 56 miles. In its upper course it passes from its source in Cavan to Lough Allen in the county of Leitrim; thence through a difficult channel, where the navigation is in part transferred to a canal, to a small expansion called Corry Lough, and, with alternations of river and lake, to Lough Forbes, in the county of Longford, on leaving which the river for a time attains an average width of 250 yards as far as Lanesborough. Here it is again merged in a lake called Lough Ree, which stretches ten miles southwards to within two miles of Athlone. At this point great natural difficulties have been overcome, and the course of the river, by Shannon Harbour and Portumna, and through the picturesque Lough Derg to Killaloe, has been so deepened and improved that a regular passenger and goods traffic is maintained. From Killaloe to Limerick the navigation, owing to the rapid fall, is again in part transferred to a canal. On approaching Limerick the river divides into two branches, and on the island thus formed stands what is known as the Irish Town, in contradistinction to the English town, of Limerick. From the city, where an extensive and commodious range of quays has been built, to the sea, the S. is navigable to sea-going vessels; and although for a distance of eight or nine miles below the city it is very shallow at low water, the navigation for the last 40 miles is free and unimpeded at all times of the tide. The entrance between Kerry Head and Loop is seven miles across. About ten miles from the entrance the river narrows to about a mile and a half in width. At present, however, the most important part of the outward navigation commences at the harbour of Foynes, which is connected by railway with Limerick, and from which steam-boats daily ply to Kilrush, Tarbert, and the intermediate stations.

Several rivers of considerable size fall into the S. during its course, as the Suck, the Brosna, the Fergus, the Maigue, and the Feale. The improvement of this river has long been regarded a measure of national importance, and was commenced under the Irish parliament. In 1837, the work was placed under a board of commissioners, by whom a sum of more than half a million was expended. It has since been transferred to the Board of Works. The navigation is open from the head of Lough Allen to Limerick, a distance of 146 miles, over 129 of which large river steamers freely ply. Much dissatisfaction, however, is expressed by the proprietors and occupiers of the banks of the river at the very imperfect and, it is believed, faulty character of the provision for drainage and the prevention of overflow; and the subject is at present again under the consideration of the government and the legislature.

SHAN-SE' (West of the Hills), a province of North-Western China, is of rugged surface, and lies on the western limits of the plain. In the north are imperial hunting-grounds. It supplies the purest iron ore and the best coal in China, besides cinnabar, copper, marble, and other minerals.



SHAN STATES, a number of tributary states in Indo-China, lying between Munnipur on the west and Yun-nan on the east, and from the parallel of 24° N. lat., south to Bankok and Cambodia. Of these the northern states are tributary to Burmah (q. v.) and the southern to Siam (q. v.). A great portion of the mountainous region of these states is called the Laos Country. The Laos races are divided into two curiously distinct subdivisions. The northern race, beyond the northern frontier of Siam, are called *Black-bellies*, from the circumstance that they tattoo themselves with figures in ink, printed on their bodies with sharp needle-like points; the southern race, mostly on and within the eastern frontier of Siam and tributary to that kingdom, are called *White-bellies*, and do not tattoo. Xieng Mai, the capital of Laos, stands on a wide plain on the right bank of the Meinam, 500 miles north of Bankok, and is said to contain 50,000 inhabitants. The number of Laocians included in Siam alone is estimated at 1,000,000. They are meek, gentle, unwarlike, and superstitious. Their chief employment is agriculture; and the principal crops raised by them are rice, maize, the sweet potato, calabashes, red pepper, melons, and other fruits. In religion they are Buddhists.

SHA'PINSHAY, one of the Orkney Islands, about 5 miles north-east of Kirkwall. It is 5 miles long and 4¼ miles in extreme breadth. The fine natural harbour of Elwick Bay on the south side is overlooked by a pleasant modern village. Pop. (1861) 973.

SHARI (i. e., *river*), the principal feeder of Lake Tsad or Tchad (q. v.).

SHARK (*Squalus*), a Linnean genus of cartilaginous fishes, now forming in Müller's system a suborder of *Plagiostomi* (q. v.), and divided into a number of families and many genera. The sharks have generally an elongated form, tapering gradually to the tail, and not much thickened in the middle. The muzzle projects over the mouth; the nostrils are situated on the under-side of the muzzle. The males have claspers. The gill-openings are lateral. There is no cartilage between the snout and the pectoral fin, as in the rays. Some of the sharks are ovoviviparous; others lay eggs, generally a pair at a time, more being produced in succession. The eggs are large in comparison with those of osseous fishes, and are of a square or oblong form, with a tough horny coat, each corner prolonged into a tendril, the tendrils being apparently of use for their entanglement amongst sea-weeds. These eggs, or at least their empty cases, are very frequently cast up by the waves on the sea-beach, and are popularly known as *Sea Purses* or *Mermaids' Purses*. Near the head of the enclosed embryo there is a slit in the case through which water enters for respiration, and there is another at the opposite end, by which it is discharged. The young fish ruptures the case at the head, where it is weaker than at any other part, and on issuing from it, carries a yolk-bag attached to its belly for its nourishment until it is able to seek food. At this stage of its existence, its respiration is also aided by filaments projecting from the gills through the gill-openings, which are absorbed as it grows older. The teeth are generally large, sharp, and formed for cutting, with the edge often serrated; but in the genus *Cestracion* (q. v.) the teeth are pavement-like; and in some genera they are small and numerous. The Angel-fish (q. v.) is ranked among the sharks, but differs from the rest in its flattened form. Some of the smaller sharks are popularly known by the names Dogfish, Hound, Tope, &c. In the articles Cestracion, Dogfish, Fox Shark, Hammer-head, Porbeagle, and Tope, some of the S. tribe are noticed. It only remains here to notice a few of the more interesting of those which do not come under any of these heads.

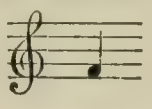
The WHITE S. (*Carcharias vulgaris*) is the most dreaded of all the monsters of the deep. The family *Carcharidæ*, to which it belongs, have two dorsal fins, the first dorsal placed over the space between the pectoral and ventral fins; they have a nictitating membrane; and have no spout-holes. In the genus *Carcharias* the snout is flattened. The white S. attains a great size; one has been caught of 37 feet in length. The body is covered with a hard skin,

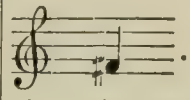
White Shark (*Carcharias vulgaris*).

and is grayish-brown above and whitish below. It is a very rare visitant of the British coasts, if indeed another species has not been mistaken for it; but is found in the Mediterranean, and is plentiful in the seas of many of the warmer parts of the world, often following ships to feed on any animal substance that may be thrown or may fall overboard, and often in its indiscriminate voracity swallowing things which are indigestible. A lady's work-box has been found in a S.'s stomach; and the papers of a slave-ship, which had been thrown overboard, in that of another. Human beings are not unfrequently its prey, and a large S. is not only capable of biting off the limb of a man, but of snapping the body in two, and has even been known to swallow a man entire. Its head is large, the mouth large and wide, furnished with a terrible apparatus of teeth, of which there are six rows in the upper jaw and four in the lower; the teeth are triangular, sometimes two inches in breadth, sharp-edged, and serrated; when not in use they are laid back in the mouth, nearly flat, but when the S. bites they are

SHARKS

brought up—or at least those of the outer rows—by means of muscles with which each tooth is independently provided. The tail, as in all the sharks, is heterocercal, but its lobes are more nearly equal than in most of them. The S. is often captured by sailors, by means of a great hook baited with a piece of meat, and attached to a chain, as the S.'s teeth readily bite through any rope. When the S. is hooked and hauled on board, great care is requisite to avoid danger both from the mouth and from the tail, the powerful action of the latter being generally interrupted by a sailor springing forward and cutting it above the fin with a hatchet. A curious method of catching the S. is practised in the South Sea Islands; a log of wood is set afloat with a strong rope attached to it, at the end of which is a noose, and the sharks gathering about it as if from curiosity, one of them may be expected soon to get its head into the noose, and is at last wearied out by the log. Formidable as the S. is, men have sometimes successfully braved it in its own element, watching its turning—as from the position of its mouth it must do—to seize its prey, and stabbing it in the belly.





The Blue S. (*Carcharias glaucus*) is much smaller than the White S., seldom exceeding eight feet in length. It is also of a more slender form. The upper parts are of a blue colour, the belly white. This species is common in the Mediterranean, and in the warmer parts of the Atlantic. It is not unfrequent on the south-western coasts of England in summer, apparently coming in pursuit of pilchards, and often doing great mischief to the nets and lines of fishermen, its sharp teeth biting through a net or line with the utmost ease.

The Basking S. (*Selache maxima*) belongs to the family *Lamnidæ*, having two dorsal fins, spout-holes, and no nictitating membrane. The snout of the Basking S. is short and blunt; the teeth are small, numerous, conical, and curved backwards. The skin is much rougher than in the White S. and Blue Shark. This species attains a great size, being sometimes 36 feet long, but it is not so thick in proportion as the White Shark. It is of a blackish-brown colour, glossed with blue. It does not exhibit a ferocious character, and is supposed to feed on medusæ, crustaceans, and the like. It is often seen swimming slowly with its dorsal fin above the surface of the water, whence it has obtained the name of *Sail-fish*. It permits itself to be quite closely approached by a boat, but on being struck with a harpoon, it plunges suddenly down, and swims off with great rapidity, so that its capture is attended with danger. It is not uncommon on the northern and western coasts of Britain.

The Greenland S. (*Scymnus borealis*) is of the family *Scymnidæ*. It has large spout-holes, two dorsal fins, no anal fin, and no nictitating membrane. It inhabits the northern seas, and is rarely seen so far south as even the northern Scottish islands. It attains a length of 14 feet or more, is thick, and tapers suddenly at the tail; the fins very small; the teeth in both jaws so arranged as to diverge from a centre. It bites and annoys whales, but feeds also on small fishes and crustaceans. When a whale has been killed, a S. will often come even whilst men are occupied in cutting off the blubber, and scoop out one great lump after another, and will return to its repast after having been severely wounded.

The rough skin of sharks is employed by joiners for polishing fine-grained wood, and for covering the hilts of swords to make them firmer in the grasp.—The flesh is coarse, but is sometimes eaten. The fins abound in gelatine, and are much used by the Chinese for making a rich gelatinous soup. Dried sharks' fins are a considerable article of import into China. The liver yields a large quantity of oil, which is now also, in some parts of the world, an article of commerce. For the sake of this oil a S. fishery is prosecuted on the coast of Ceylon.

Fossil Sharks make their first appearance in the Oolitic rocks, from which eight species have been described. They become more numerous in the Cretaceous deposits, in which no less than 60 species have been found. In the Tertiary strata, their remains are still more abundant. But as the determination of fossil species depends entirely on the teeth, which, with the exception of the spines and vertebræ, are the only portions preserved, it is probable that the species and genera are too greatly multiplied.

SHARP, a sign ♯ in Music, which, when prefixed to a note, elevates it by a semitone in the scale, raising, for example, F  to F sharp  . When placed at the beginning of a piece of music, it denotes that all the notes on the line or space on which it is placed, and their octaves above and below, are to be played sharp. A double sharp × raises a note two semitones.

SHARP, James, Archbishop of St Andrews, was the son of William Sharp, sheriff-clerk of Banffshire, and was born in the castle of Banff, May 1618. Educated for the church at the University of Aberdeen, where he attained distinction as a student, and where he is said (on the authority of a tract, entitled *A True and Impartial Account of the Life of the Most Reverend Father in God, Dr James Sharp, Archbishop of St Andrews*, published in 1719) to have protested against the 'Solemn League and Covenant;' he afterwards visited England, and became acquainted with several eminent English divines, such as Hammond, Sanderson, and Taylor. Returning to Scotland, he was appointed a professor of philosophy at St Andrews, through the influence of the Earl of Rothes, and soon after minister of the parish of Crail, an office which he held during the ascendency of Cromwell. In August 1651, when Monk was reducing Scotland to obedience, he was carried off, along with several other ministers, to England. S. quickly regained his liberty, and he possessed, for some years, the confidence of the more moderate party in the church. In 1656, he was chosen by them to plead their cause in London before the Protector, against the Rev. James Guthrie, a leader of the extreme section (the Protestors or Remonstrators), which he did with so much dexterity, that Cromwell is reported to have said: 'That gentleman, after the Scotch way, ought to be termed Sharp of that Ilk.' When the Restoration was on the eve of happening, S. was appointed by the moderate party to act as its representative in the negotiations opened up with Monk and the king. This is the crucial period of his career, and on the view we take of his motives depends our whole estimate of his character. Was he sincere, or did he mean to betray the church to which he owed allegiance? Presbyterian writers are nearly unanimous in affirming his perfidy, although the evidence is doubtful. Among the first things the Scottish parliament that met 1st January 1661 did, was to repeal or rescind every act passed since 1638, in consequence of which Episcopacy remained the Church of Scotland, as 'settled by law'—a dishonourable evasion of a promise made by Charles in a letter written to the Presbytery of Edinburgh

in August 1660. Soon after, at a council held in Whitehall, S. was nominated Archbishop of St Andrews, and having gone up to London, he was there formally consecrated by the Bishop of London and three other prelates. His government of the Scottish church was tyrannical and oppressive; and in consequence he became an object of hatred to most of his countrymen. When one Mitchell, a conventicle preacher, fired a pistol at him in the streets of Edinburgh, the populace allowed the intending assassin to walk quietly off, without making a single effort to arrest him. Finally, S. was assassinated on Magus Moor, near St Andrews, 3d May 1679, by a band of fanatical Covenanters. In defence of S., the utmost that can be said is, that he was simply an ambitious ecclesiastic (of plausible and courtly manners), who had no belief in the 'divine right' of Presbytery, and who thought that if England were resolved to remain Episcopalian, it would be very much better if Scotland were to adopt the same form of church-government, and that if there must be an Archbishop of St Andrews, there was no reason why he should not be the person. This theory is certainly a more sober one than the usual melodramatic Covenanting view, which makes him out to be 'a conscious villain,' who persecuted his old friends the more fiercely that he knew they were in the *right* and he in the *wrong*.

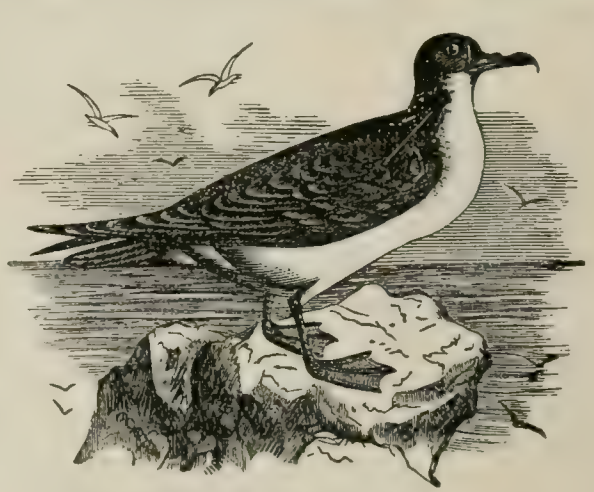
SHA'RPSHOOTERS, an old term applied in the army to riflemen. It is now appropriated to naval use, to the men stationed in the top to annoy those on the deck of an enemy's vessel.

SHÂSTRA or SHÂSTER, but more correctly written S'ÂSTRA (from the Sanscrit *s'âs*, to teach), means literally a book; but the term is especially applied to the *authoritative*, religious and legal, books of the Hindus. See SANSCRIT LITERATURE.

SHAT-EL-ARAB. See EUPHRATES.

SHAVE-GRASS. See EQUISETUM.

SHAWL-MANUFACTURE. Perhaps no garment is of higher antiquity than the shawl; indeed, its simplicity of form would lead us to infer that it was the earliest in use. But of its manufacture we have no distinct account until the reign of the Emperor Jelal-ed-din-Mohammed Akbar, in 1556, when the celebrated Cashmere shawls were amongst the most important manufactures of the world, and were thought worthy to be minutely described in the *Ayin-i-Akbari*, or the 'Institutes of the Emperor;' in that work, four distinct classes of shawls, all of goat's wool, are described. The 1st were of remarkable lightness and softness, and were usually self-coloured, and made of the wool undyed; the 2d were woven of wool in the natural colours—viz., white, black, and gray—these were probably arranged so as to form a plaid pattern similar to the shepherd's plaid of Scotland, which is of oriental origin; the 3d were called *gold-leaved*, probably from being embroidered with that material; and the 4th were long shawl-pieces large enough to enwrap the whole body. So carefully was this manufacture fostered, that it received the chief attention of the emperor, and every shawl manufactured was carefully described and registered, and the number of manufacturers was so great that in Lahore alone it is stated there were upwards of 1000. The manufacture, in later times, passed through many vicissitudes, and during last century, it declined greatly; but in 1809, it had again risen, and there were then about 16,000 looms at work. From 4000 to 5000 of these beautiful fabrics are annually imported into Great Britain; but admirable imitations are now produced by the British manufacturers, and by the French, as well as by those of Austria and Prussia. The true Cashmere shawls are woven in many pieces, and joined together with great artistic skill; those of Britain and France are, however, woven in one piece, the loom being worked by hand, and of course furnished with a Jacquard machine for the production of the pattern. Besides the Cashmere shawls and their European imitations, there is an infinite variety of shawls made of various materials—as silk plain, embroidered, and in the form of crape; thread, cotton, and silk lace; and wool in a great variety of styles.



SHEA. See BASSIA.

SHEA'RING-MACHINE, a machine used in the preparation of woven woollen fabrics. See WOOLLEN MANUFACTURES.

SHEARS of various kinds are amongst the implements used in gardening. They are scissors on a large scale, variously modified to suit their various purposes, such as pruning trees, hedges, box-edgings, the verges of grass plots, &c. They are often furnished with long wooden handles, and a spring is sometimes fixed between the handles. A kind used for removing small branches of fruit-trees has one blade made to slide along the other whilst they are brought together, so that it makes a cut as clean and smooth as that of a knife.

SHEAR-STEEL. See IRON.

SHEA'RWATER (*Puffinus*), a genus of *Procellaridæ* (see PETREL), differing from petrels in having the tip of the lower mandible curved downwards, and the nostrils opening separately and not by a common tube. The bill is as long as the head, or longer, the upper mandible compressed and curved at the point. The legs are of moderate length, the tarsi compressed, the hind-toe rudimentary. The wings are long and pointed. The shearwaters spend their lives mostly on the ocean, rarely visiting the shore except for the purpose of incubation.—The GREATER, WANDERING, or CINEREOUS S. (*P. cinereus* or *major*) is about 18 inches long, the upper parts blackish-brown; the throat, breast, and belly gray. Young birds are entirely brown, the upper parts darkest. This species is frequently seen on the south-western coasts of Britain. It is very abundant on those of Newfoundland.—The MANX S. (*P. Anglorum*) is much more common on the British

Manx Shearwater (*Puffinus Anglorum*).

coasts, and is found also in more northern regions. It is about 14 inches long, grayish-black, the neck mottled with gray, the throat and all the under parts white. It breeds on islets, in rabbit-burrows, or in crevices of the rocks.—There are several other species in warmer climates.—The name S. is sometimes also given to the Skimmers.

SHEATH-BILL (*Chionis*), a genus of birds of the family *Chionidæ*, placed by many naturalists among the *Grallæ*, but by others regarded as belonging to the *Gallinaceous* order, and ranked by Mr Swainson among *Columbidæ*. The legs are stout and moderately long, the toes much resemble those of the common fowl, but the fore-toes are united at the base. The bill is thick and conical, and the base is covered by a horny sheath, which the bird has the power of raising and depressing. The WHITE S. (*C. alba*) inhabits the shores of Australia, New Zealand, and neighbouring islands, and feeds on molluscs, crustaceans, and whatever animal substance is thrown up by the waves. It is about the size of a partridge.

SHEATHING is a protection for the wooden planking of the immersed portion of a ship from the attacks of the teredo and other worms, molluscs, and marine animals, which, especially in hot climates, adhere to the bottom and eat into the timber, while they retard the vessel's progress. As early as the time of Trajan, sheets of lead were used as sheathing. Thin deal boards, about half an inch thick, were in more modern times nailed on and frequently changed; but about the commencement of the present century, plates of copper were introduced, which have been found most effectual, though expensive. The gradual oxidation of the copper by the action of the sea-water produces a sort of poison, which prevents any marine animal from adhering, and keeps a clean bottom. The copper, however, slowly wears away in this oxidation, and requires renewing after a few years. To prevent this loss various methods have been devised. Sir H. Davy applied what he called protectors, consisting of pieces of iron and zinc on different parts of the copper; the action of the water on the two metals produced a small galvanic current, which prevented the copper from oxidising; but it became forthwith encased in barnacles and weeds. For ships stationary in harbour, as hulks, ships-in-ordinary, &c., this system of protection answers well; but it fails for sea-going vessels, together with many other protecting mixtures which have been tried, from the fact that in proportion as the copper is saved from oxidation, by so much does it cease to repel the incrustations which always threaten it.

SHEAVE. See PULLEY.

SHE'BA. See SABÆANS.

SHEBOY'GAN, a town and port of Wisconsin, U. S., on the west bank of Lake Michigan, at the mouth of the Sheboygan River, 60 miles north of Milwaukee. It was settled in 1836, has a good harbour, with mills at Sheboygan Falls, 6 miles above, and a large trade in wheat and timber. Pop. (1870) 5310.

SHECHI'NAH (from *shachan*, to reside, rest), a word used in post-biblical times by the Jews, and adopted by the early Christian writers: expressive of the presence of the Divine Majesty, in Heaven, among the people of Israel, or in the Sanctuary. It is first found used in the Chaldee versions (Targums) as a kind of periphrasis for the person of God, wherever it is mentioned in the Bible as corporeal: thus being a kind of spiritual interpretation of anthropomorphism. The S. is not supposed to have dwelt in the second temple, but it is to return with the Messiah. The particular place where the S. was supposed to dwell was the 'mercy-seat between the cherubim.' The cherubim or other angels were always more or less connected with the S. itself, as in the phrases 'the heavenly hosts,' 'hosts of saints,' &c., accompanying the Divine presence. The first mention of the word is found in the Targum Jerushalmi, Gen. iii. 24—'And He expelled Adam, and caused to reside the splendour of his Shechinah from the beginning at the east of the garden of Eden, above the two cherubim.' (Second recension: 'between the two cherubim.') Another characteristic instance of its use is found in the version of Onkelos, Deut. iii. 24—'Thou art God, Thy divine Shechinah is in Heaven above, and rules on earth below.'

SHEEP (*Ovis*), a genus of ruminant quadrupeds of the family *Capridæ*, so nearly allied to goats that the propriety of generic distinction is very doubtful. They differ from goats in having the outline of the face more or less arched and convex; the horns spiral, sometimes very large in the males—in domestication, however, often wanting in the female, and also in the males of some breeds; the chin destitute of a beard; a sac or pit between the toes of each foot, lined with hair, and secreting a fatty matter. It is supposed by some that all the wild sheep existing in different parts of the world are mere varieties of one species, but of this there is no sufficient proof, nor is there anything more than unsupported conjecture in any of the opinions advanced concerning the origin of the domestic sheep, such, for example, as that which refers it to the Moufflon (q. v.), or that which ascribes different domesticated breeds to different wild originals, as the Moufflon and the Argali (q. v.). In opposition to all such conjectures, it has been remarked that the tail of all the known wild sheep is very short, whereas that of the common sheep, if not mutilated by the shepherd, almost reaches the ground, and there is no known instance of the tail of any kind of quadruped becoming longer by domestication. It is not impossible that the common sheep may still exist, in a wild state, as yet unknown to naturalists, in the little explored regions of Central Asia.

All the wild sheep known are natives either of mountainous regions or of dry and elevated tablelands. They are gregarious, a character which the domesticated sheep fully retains. They are generally seen in small flocks, and are not easily approached, taking refuge in flight, a sharp whistling sound, emitted by one of the rams, serving as an alarm to the whole flock; although they are very capable of making a vigorous defence when driven to close combat. A ram of the domestic species is, indeed, able to sustain a conflict with a bull, taking advantage of his far greater agility, and butting against his foe with his strongly armed forehead. A ram has been known to throw a bull on the ground at the first onset, and is always ready to defend himself and his companions against a dog. Many rams exhibit great pugnacity, and the timidity often ascribed to sheep is chiefly to be seen in the ewes of the hornless breeds. Sheep differ from goats in their mode of fighting. Goats rear themselves on their hind-legs, and throw themselves sideways on their adversary, to bring the points of their horns to bear; sheep rush straight at him, a mode which better suits the different style of armature of the head.

All the wild sheep have short wool, with an outer clothing of long and nearly straight hair. But even the long hair—at least on the Moufflon—has the peculiar character of wool, in that roughness of surface which gives it the property of *felting* (see HAIR and FELT). One effect of domestication in the common sheep has been to cause the disappearance of the outer long hair, and to produce instead an increase of the length and abundance of the wool, an object of great importance to the sheep-farmer. In neglected breeds of the common sheep, the two kinds of hair or wool are very apparent. In some tropical climates, the sheep loses its abundant fleece,

and is covered with hair little longer than that of the ox.

Although not equal to goats in their adaptation to rocky steeps, and not endowed with such power of leaping from crag to crag, sheep exhibit a strong disposition to seek their food in places where no animal not very agile and sure-footed could venture; and those of the domesticated breeds which retain most of their original wildness are thus adapted to situations in which otherwise the pasture would be of no value to man. Every one who has seen the lambs frisking on a Highland hill, must have admired their nimble movements in places where a herd-boy could with difficulty scramble. In fine weather, sheep ascend the heights; and in cold and stormy weather, they repair to the lower grounds.

Of the wild sheep, two species, the Argali and the Moufflon or Musmon, have been already separately noticed. Another very interesting species is the Rocky Mountain Sheep, or Big-Horn (*O. montana*) of North America, the only indigenous American

Rocky Mountain Sheep.

representative of this genus. It is equal in size to the argali, which it much resembles also in its general appearance, and in the size and curvature of its horns. The horns of the old rams attain so great a size, and are so much curved downwards and forwards, that they effectually prevent the animal from feeding on level ground. The abode of this species is in the most craggy and inaccessible parts of the Rocky Mountains. The flesh is of the very finest quality. The wool is very fine, and fully an inch and a half long; it is completely concealed by long hairs. The general colour is brown, paler on the lower parts; the old rams are almost white in spring. No attempt seems yet to have been made to domesticate the Rocky Mountain Sheep, although Professor Jamieson of Edinburgh recommended its introduction into Britain in 1818.—The Aoudad (*O. tragelaphus*) is a native of the north of Africa, inhabiting chiefly the lofty parts of the Atlas Mountains. It is sometimes called the Bearded Argali, although it has no beard on the chin; but the throat, the chest, and the front of the forelegs are remarkably adorned with long shaggy hair. On other parts the hair is comparatively short, with an underclothing of short wool. The colour is a uniform reddish-yellow. The tail is longer than in the other wild species, and is terminated by a kind of tuft of long hairs. The horns are not so large as in the other wild species. In size, the Aoudad exceeds the Moufflon, but is not equal to the Argali. The French call it *Moufflon à mouchettes*, or Ruffled Moufflon, from the long hair of its forelegs.

The Common Sheep (*O. aries*) was probably the first animal domesticated by man. We are told in the book of Genesis that Abel was 'a keeper of sheep,' and that he brought an offering unto the Lord 'of the firstlings of his flock and of the fat thereof.' And from that time until the death of Christ, lambs continued to be the most frequent sacrificial offerings, both amongst the patriarchs and the Jews. The felting and weaving of wool were unquestionably among the earliest of the arts. The wool was probably at first pulled from the skin, a rude and even cruel practice, which still subsists in some countries, and was not long ago relinquished in the Orkney Islands; but we read in Genesis xxxviii. of Judah shearing his sheep, and there is abundance of other evidence that this better mode of obtaining the fleece has been in use from remote antiquity. Almost every part of the sheep is useful, and is employed for purposes similar to those of corresponding parts of the ox. The leather made of the skin is much employed in bookbinding, and for making gloves. In patriarchal times, the milk was much used, as it still is in some countries; it is richer than cow's milk, and the cheese made of it has a sharp taste and strong flavour, which, however, are greatly relished by some. In Britain, except in the mountainous parts of Scotland and in Wales, the milk of the sheep is now scarcely regarded, and cheese is almost never made from it. In some mountainous parts of India the sheep is even used as a beast of burden, carrying loads of from 35 to 40 pounds, over rough tracks, and up steep crags, where almost no other animal could be employed.

The sheep is not generally reputed to possess much intelligence; but those who watch sheep carefully, or keep them as pets, find them very far from being devoid of it. Their reputation of stupidity seems to be very much founded on their habit of following, without scruple, the leader of the flock; so that when sheep are being driven across a narrow bridge, or where a fence separates the road from a precipice, if anything occur to deter them from proceeding in the proper path, and one break over the fence or parapet, the whole flock may be expected to follow, as has sometimes happened, to their utter destruction. Of this instinct, the shepherds of the East have taken advantage, bestowing special care upon the leaders of the flock, which follow readily on their call, and the whole flock is thus under the shepherd's command. The allusions in the sacred Scriptures to the flock following the shepherd, and the shepherd calling his sheep by name, are as appropriate to the customs of the East at the present day as in the times when they were written. The management of sheep in Britain and other western countries is of an entirely different character.

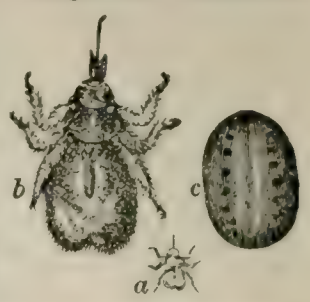
The sheep generally brings forth one lamb at a birth, frequently two; sometimes three, and rarely four or five. The lambing season is when spring is so far advanced that the young lambs are safe from the cold and storms of winter. The care of the sheep-farmer, however, modifies the course of nature, when his object is to send lambs to market at an earlier season than would be possible if the sheep were left without shelter or other food than the natural pasture. The lamb is suckled for nearly three months, and at the end of this time the annual sheep-shearing takes place.

The ancient Britons seem to have possessed sheep before the Roman invasion. During the period of Roman dominion, Britain became famous for the production of wool, and British woollen goods were much valued in Rome. Winchester early became the great seat of the woollen manufacture, and continued to be so for centuries. The great object of sheep-farming in Britain at this time was the production

of wool. The demand for butcher-meat has now raised the value of mutton and lamb so much, that the farmer finds it profitable to devote much of his attention to the supply of the market with these articles; and those breeds of sheep are reckoned most valuable which are most suitable for this purpose, even although the fineness of the wool is inferior to what might be obtained if it were the one great object of regard, and to what is imported from distant parts of the world. The quantity of the wool and the length of its fibres, however, compensate in a great measure for its inferior fineness. Wool is the chief object of the Australian sheep-farmer, and the introduction of the Merino Sheep has been of great importance in the improvement of its quality. When there was no food for sheep but the natural pasture, sheep could not be fattened for the market except during summer, and not until they had attained an age of three, four, or five years, whereas much of the mutton now consumed is the flesh of sheep not more than two years old; the sheep being fattened by the aid of turnips, mangold, oil-cake, &c. If the quality of the mutton is not quite equal to that of older sheep, the supply is much greater, as well as the profit to the farmer. In weight and fatness, the sheep of the best breeds far exceed anything known until recent times.

The young branches of heath, and in lower situations, the shoots of furze, often serve as food for sheep, when the supply of grass fails. Sheep delight in the short grass and peculiar herbage of hill pastures and bare downs; and the mutton produced in such pastures, and by the breeds most suitable to them, is of superior quality to that of the large fat sheep fed on richer soils. The latter are also more liable to many diseases, particularly where the ground is at all moist. Aromatic and bitter herbs are particularly relished by sheep.

The breeds of sheep are very numerous, and very different. The valuable Merino (q. v.) Sheep has been already noticed.—The Black-faced Sheep of the Highlands of Scotland and of the north of



Black-faced Ewe and Ram.

England, is perhaps as near the original type as any existing breed. Both male and female have horns; those of the ram large, with two or more spiral twists, those of the ewe much smaller, and little twisted. The face and legs are black. The Black-faced Sheep is robust, very active, and hardy; enduring the rigours of a severe winter when sheep of the most of the breeds common in Britain would perish. It has a bright, quick eye, with an expression very different from that softness which is seen in many of the breeds preferred for lower grounds and better pastures. The wool is long and coarse, and the weight of the fleece not great; but the mutton is of the finest quality; and on this account, and its hardiness, this breed is preferred to any other in many mountainous districts and on rough elevated moors.—The Welsh Sheep is much smaller than the Black-faced; both sexes horned; the colour various; the mutton highly esteemed; the fleece seldom weighs two pounds.—A similar small breed, with shorter and remarkably broad tail, hornless, or with short and little twisted horns, has long existed in the Shetland and Orkney Islands; its wool affording the material for the manufacture of Shetland hose. The Shetland and Orkney sheep are very hardy, and in winter feed much on seaweed.—Smaller than either of these, and, indeed, remarkably diminutive, is the hornless Breton Sheep.—The Forest Sheep of England, so called from being pastured in the royal forests, has now in most places been supplanted by other breeds. They are still to be seen on the barren grounds between the British and Bristol Channels; and the mutton is in much request in the London market. The original Forest Sheep was generally small, with face and legs russet brown or gray, wild, restless, and difficult to fatten, but producing wool of fine quality.—The Dorset Sheep is one of the best of the old English upland breeds. Both sexes have small horns. The wool and mutton are of medium quality; but the ewes are remarkable for their fecundity, and the abundance of their milk; and this breed is valued as affording a supply of early lamb for the London market.—The Ryeland Sheep has long existed in Herefordshire and some neighbouring counties of England. It is small, short-limbed, white, hornless; produces excellent mutton; and before the introduction of Merino wool, its wool was preferred to every other kind for the manufacture of the finest broadcloths.—The Cheviot Sheep has existed from time immemorial on the Cheviot Hills, and is now very widely diffused over a considerable part of England and almost all parts of Scotland, being hardy and well adapted for high grounds, although it is inferior in hardiness to the Black-faced, which has been restored to its place, after the losses experienced in severe winters, on many of the highest and coldest farms where the Cheviot had for a time supplanted it. The Cheviot greatly excels it both in size and in the value of the fleece; but requires a richer pasture. Both sexes are hornless. The general figure is longer than that of the Black-faced sheep. The colour is white, the face and legs occasionally mottled with gray. The fleece weighs from three to four pounds. Great attention has for many years been devoted to the improvement of this breed.—The Leicester Sheep is another of the most valuable breeds. This breed, as it now exists, is a result of the skill and care of Mr Bakewell, who, soon after the middle of last century, began to make experiments for the improvement of the old Leicester sheep—a large, coarse-boned sheep, not easily fattened, and with coarse long wool, of which, however, the fleece weighed about ten pounds. The new Leicester sheep has wool moderately long, of better quality, the average weight of the fleece about seven or eight pounds; and is easily rendered very fat. The colour is white. Both sexes are hornless. The Leicester sheep is now common in all but the mountainous parts of Britain, and other breeds have been improved by crossing with it, particularly various breeds of long-woolled sheep, which have long existed in different parts of England, as those of Lincolnshire, Romney Marsh, &c.—A famous long-woolled breed is that called the Cotswold or Gloucester, the wool of which was in great esteem in the 14th and 15th centuries,

bearing a higher price than any other wool. In 1464, Edward IV. sent a present of Cotswold rams to Henry of Castile; and in 1468 a similar present was sent to John of Aragon. The Cotswold breed, however, as it at present exists, has been modified by crossing with the Leicester, and produces shorter wool and better mutton than in former times.—The SOUTH DOWN SHEEP is the only other British breed that requires special notice for its importance to the farmer. It has recently been improved with the utmost care. The colour is generally white, but black is not rare; and the face and legs are generally dun, black, or speckled. Both sexes are hornless. The wool is short, close, and curled. The South Down derives its origin and name from the chalky *downs* of the south of England; but is now common throughout England and the south of Scotland. It is not suited to very cold and exposed situations.

The ICELAND SHEEP is remarkable for very frequently having three, four, or five horns. The same peculiarity, or monstrosity, as it may be deemed, is exhibited by the sheep of some of the most northern parts of Russia. The Iceland sheep has a double covering of long and short wool. Its flesh is of the very finest quality.—The north of Africa possesses a breed of sheep with legs of great length, pendulous ears, and much arched face; the wool short and curled, except on the neck and shoulders, which have a kind of mane.—India has also a hornless breed, with pendulous ears, short tail, and very fine much curled wool.—The BROAD-TAILED or FAT-TAILED SHEEP is found in many parts of Asia, as in Syria, India, and China, also in Barbary, and is now very abundant in the colony of the Cape of Good Hope. It is rather of small size, with soft and short wool. Its chief characteristic is the enormous development of the tail, by the accumulation of a mass of fat on each side, so great that the tail has been known to weigh 70 or 80 pounds. The tail is highly esteemed as a delicacy, and to protect it from being injured by dragging on the ground, the shepherd sometimes attaches a board to it, or even a small carriage with wheels. The fat of the tail is often used instead of butter. It is less solid than other fat.—The FAT-RUMPED SHEEP of Southern Tartary has a similar accumulation of fat on the rump, falling down in two great masses behind, and often entirely concealing the short tail.—The ASTRAKHAN or BUCHARIAN SHEEP has the wool twisted in spiral curls, and of very fine quality. The lamb skins, so much in request amongst furriers, are in great part produced by this breed; but partly also by the CIRCASSIAN SHEEP, which is reared on Mount Caucasus and adjoining regions, where the shepherds sew up the lambs as soon as they are born in bandages of coarse linen, and pour warm water over them every day, to make the wool soft and sleek, and to lay it in glossy ringlets, the bandage being gradually let out to suit the increasing size of the animal. This fur is much used for lining dresses. The Circassian sheep has a remarkably long tail, covered with fine long wool, which trails on the ground.—The WALLACHIAN SHEEP, common in Hungary, as well as in the country from which it derives its name, is distinguished by the magnitude of its horns, and their direction. They make one great spiral turn, and then generally rise up from the head to a great height, twisting round as they rise. The wool is soft, and is concealed by long hair.

SHEEP-LOUSE, or SHEEP-TICK, or (in Scotland) KAID (*Melophagus ovinus*), an insect of the family *Hippoboscidæ*, to which also the Forest Fly belongs, ranked in the order *Diptera*, although in this genus the wings are completely wanting. It lives among the wool of sheep, and particularly of lambs, sucking the blood of the animal, and is most abundant in the early part of summer. Where it fixes its head in the skin, a large round tumour is formed. Its body is very compressed and smooth, of a rusty colour, the head and thorax small, the abdomen large. The female does not lay eggs, but, like the other *Hippoboscidæ*, hatches the egg and nourishes the larva within her own body, till it passes into the pupa state, when it is deposited, oval-shaped and shining, fastened to the wool of the sheep. Sheep-farmers use various washes or *dips* for the destruction of these creatures, many of which are arsenical. A patent was obtained a few years since for a sheep-dip, of which Carbolic Acid is a principal ingredient.

Sheep-louse (*Melophagus ovinus*):
a, natural size; *b*, magnified; *c*, the pupa, magnified.

SHEEP'S-HEAD (*Archosargus ovis*), a fish of the family *Sparidæ*, plentiful in the latter part of summer on some parts of the coast of North America, and highly esteemed for the table. It sometimes attains a weight of 14 or 15 pounds. A very large fish is sometimes sold in the New York market for a price equal to four or five pounds sterling. The fishery is therefore of some importance. Nets are used, and many fish are often taken at a single haul, which are immediately packed in ice for the market. It is difficult to take the S. with a line, as its cutting teeth snap the line asunder. The genus *Sargus* has cutting front teeth, and round teeth in the back of the mouth. *S. Rondeletii* inhabits the Mediterranean, and has been esteemed for the table from ancient times. The *Sargi* feed on shell-fish and the smaller crustaceans, which they easily crush with their round teeth; partly also on sea-weeds.

SHEEP-STEALING, in England, is felony, and is punishable with penal servitude from three to fourteen years, or imprisonment for two years. In Scotland, it is a capital offence, though, for some time, it has never been punished capitally.

SHEERNE'SS, a seaport and naval arsenal in the county of Kent, stands on the north-west extremity of the Isle of Sheppey, at the confluence of the Thames and Medway, 11 miles east-north-east of Chatham. It consists of four divisions, Blue-Town, Mile-Town, Marine-Town, and Westminster, and of these the first is within the limits of the garrison. The dockyard, much extended and improved within recent years, is now one of the finest in Europe. It covers 60 acres, comprising wet and dry docks, immense storehouses, and official residences. The harbour is usually crowded with vessels of all descriptions. An extensive oyster-fishery is carried on in the vicinity, from which as many as 50,000 bushels of 'natives' have been sent to London in one season. At Garrison Point is the residence of the port-admiral, the telegraph, coast-guard station, and barracks. The chief trade is in supplying the requirements of the employees in the various government establishments, and in the export of corn seeds and oysters. The neighbourhood was once thought to be very unhealthy, but of late years important sanitary works have been carried out, and there are now few towns the population of which enjoy better health. Since the provision of direct railway communication with all parts of England, the town is much visited during the summer on account of the excellent sea-

bathing there, which is under the management of a local joint-stock company. The beach and cliffs are a favourite resort for ramblers. Pop. (1861) 12,015. S. was captured by the Dutch under De Ruyter in 1667, and here the mutiny of the Nore burst forth in 1798.

SHEERS. The elemental form of a pair of sheers consists in two spars fastened together near the top, with a pulley at the point of junction, and held by a rope, fastened to any convenient object, in such a position that the weight lifted hangs nearly between the spars. This forms an easily improvised crane. An apparatus of this kind, of great height and strength, is used for masting vessels. In the principal dockyards, there are tall

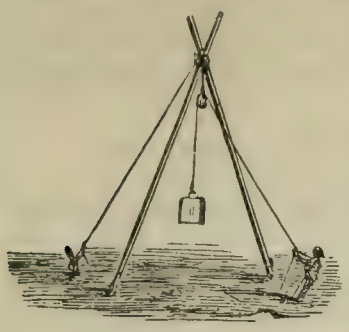


Fig. 1.

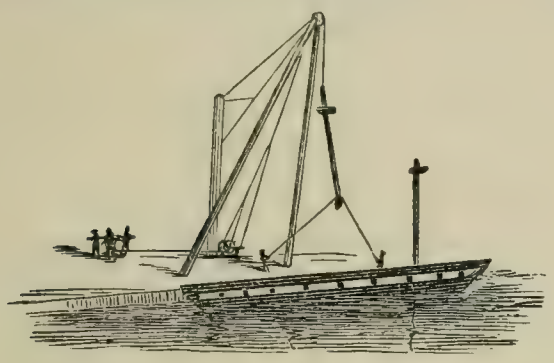

Fig. 2.

permanent sheers, mounted either on the side of a masting-dock or on a floating sheer-hulk.

SHEET, on Shipboard, is the rope by which each of the lower corners of a square-sail, or the after-corner of a fore-and-aft sail, is held down, in order that the sail may be tightened to the wind.

SHEETING, a cloth made of flax or cotton, and used for bed-linen. It is chiefly made in Ireland in or near Belfast, and in Scotland. The term sheeting is also applied to the coarse hempen cloth used for making Tarpaulings (q. v.).

SHEFFIELD, an important manufacturing town and parliamentary borough, in the West Riding of Yorkshire, and capital of an independent district, called Hallamshire (see SHIRE); it is picturesquely situated on several hills that slope towards the confluence of the rivers Sheaf and Don, 162½ miles north-north-west of London by the Great Northern Railway, and 50 miles south-south-west of York. The town, generally, is well built, although, on account of the smoke with which it is enveloped, it presents a dingy appearance as contrasted with the surrounding beautiful scenery. It possesses many fine public buildings, such as the original parish church, supposed to have been erected in the reign of Henry I., 240 feet long by 130 feet broad, with a central tower surmounted by a lofty spire; St Mary's Catholic Church, surmounted by a tower 200 feet high; the town-hall, cutlers' hall, corn exchange; the new market-hall, or Norfolk Market, with a roof of glass and iron, erected by the Duke of Norfolk at a cost of about £40,000; music-hall, assembly rooms, theatres, &c. There are extensive botanic gardens, and a fine cemetery about a mile from the town. There are 25 churches belonging to the establishment, each of which represents a separate parochial district; 3 Roman Catholic churches; and a great many other places of worship belonging to the Methodists, Baptists, Independents, and other dissenting bodies. There are monuments to Ebenezer Elliot, James Montgomery, and the soldiers belonging to S. who died in the Crimea. There are numerous educational establishments, such as the Free Grammar School, the Collegiate School, the Wesley College, a Lancasterian and many national schools, free writing-schools, school of art, besides denominational schools, &c.; also a Mechanics' Institution, established in 1832. The Mechanics' Library (1828) is now merged into the Free Library, which contains upwards of 11,000 vols. There are likewise many charitable institutions.

As far back as the time of Chaucer, S. was noted for the manufacture of cutlery; and at the present day, an endless variety of articles in brass, iron, and steel, is produced at the many manufactories with which the town abounds; such as knives of every description, silver and plated articles, Britannia metal goods, coach-springs, spades, spindles, hammers, files, saws, boilers, stoves, grates, buttons, &c. Amongst the new branches of trade are, electro-plating in gold and silver, and the manufacture of iron plates for the armour-plating of ships-of-war, which are extensively produced by several manufactories. The conversion of iron into steel by both the old and new processes is one of the largest and most lucrative branches of the trade of Sheffield. Steam-power is extensively employed. The river Don, which is navigable up to within 3 miles of the town, and the canal in connection with it, along with several important lines of railway communicating with the town, afford ample means of developing and improving the resources of Sheffield. Coal abounds in the neighbourhood. The borough was incorporated in 1843, and returns two members to parliament, the pop. in 1865 being 207,579. Of Sheffield Castle, nothing now remains. Mary Queen of Scots was imprisoned in Sheffield Manor House, about two miles from the town, for 12 or 14 years.

SHEIK (Arab., elder, aged person), a title of reverence, applied chiefly to a learned man, or a reputed saint, but also used sometimes as an ordinary title of respect, like the European Mr, Herr, &c. before the name. It is, however, only given to a Moslem. The Sheikh Al-Islam is the chief Mufti (q. v.) of Mohammedanism at Constantinople: a title supposed to have been first assumed by Mohammed II. at his conquest of Constantinople in 1453, when this place became the seat of his empire. The Sheikh of Mecca, by virtue of his supposed descent from the prophet, levies a kind of tribute on all the pilgrims to the Kaaba. The term is also applied to heads of Mohammedan monasteries (our abbot or prior), and to the higher order of religious preachers. Sheikh Al-Gebal (Ancient of the Mountain) is the name of the prince of the Assassins (q. v.), or those Ismaelites of Irak, who undertook to assassinate all those whom their chief would pronounce to be his enemies.

SHE'KEL (*siklos*, from *shakal*, to weigh), originally a certain standard weight in use among the ancient Hebrews, by which the value of metals, metal vessels, and other things was fixed. Gradually it became a normal piece of money, both in gold and silver, marked in some way or other as a coin, although not stamped. The gifts to the sanctuary, the fines, the taxes, the prices of merchandise, are all reckoned in the Old Testament by the shekel, not counted but weighed. Three different

kinds of gold, silver, and copper shekels are mentioned: the common shekel, the shekel of the sanctuary (probably of double value), and the shekel of royal weight. Besides these, there was a half-shekel (*beka*), and a fourth-shekel. The sacred shekel was equal to 20 geras (beans), and 3000 sacred shekels made a talent. The gold shekel is reckoned approximatively to contain 161 Troy grains, the silver shekel 275. During the Babylonian exile, the Persian money (*dariks*) was used by the captives; nor do they seem to have afterwards used any but the coin of their foreign rulers. It was first under the Maccabæans that national money began to be struck, adorned with sacred emblems, and with inscriptions in the native language and characters. De Saulcy alone assumes, without much show of reason, Jewish coins to have existed from the time of Alexander the Great. Simon, the 'prince and high-priest,' received, according to 1 Macc. xv. 16, the permission from Antiochus VII. to strike coin in 138 B.C. The emblems are sacred branches, sheaves, flowers, vases, &c., and the legend (in a peculiarly archaic ['Samaritan'] alphabet) contains the date, the name of the Jewish ruler, and the inscriptions 'Shekel of Israel,' 'Jerusalem the Holy,' 'Redemption of Israel.' The latest coins with Hebrew inscriptions date from the revolution of Bar Cochba under Hadrian. The value of the silver shekel is reckoned to be something over two shillings.

SHELBURNE, William Petty, Earl of, son of the first earl, and descendant of Sir W. Petty, founder of the science of political arithmetic, was born May 1737, and commenced his political career in 1761 by entering the House of Commons as member for Wycombe, but only sat for a few weeks, the death of his father having called him to the House of Lords. When Mr G. Grenville succeeded Bute in 1763, S., whose talents had made him remarked, although only 26, was placed at the head of the Board of Trade. When Chatham formed his second administration in 1766, he made S. one of the Secretaries of State, although not yet thirty. Upon the fall of Lord North's ministry in 1782, George III. sent for S., and proposed to him to form a government. He declined, not being the head of a party, and was sent by the king to the Marquis of Rockingham with an offer of the Treasury, himself to be one of the Secretaries of State. According to Earl Russell, in his *Life of C. J. Fox*, it soon appeared that S. was not so much the colleague as the rival of Lord Rockingham, the chosen minister of the court, and the head of a separate party in the cabinet. Upon the death of Rockingham in 1782, the king sent at once for S., and offered him the Treasury, which he accepted without consulting his colleagues. Fox thereupon resigned, and S. introduced William Pitt, then only 23, into office as his Chancellor of the Exchequer. S.'s ministry, on the occasion of the king's announcement of his determination to concede the independence of the American colonies, found itself outvoted by the coalition between Fox and Lord North. He resigned, and the coalition ministry took his place, but soon broke up. The nation expected that the king on this event would have sent for S., but William Pitt received the splendid prize, and S. was consoled by the coronet of a marquis (of Lansdowne). During the later years of his life, his health was delicate, and he withdrew from public life; but he came forward as a strong supporter of the union with Ireland. He indulged his tastes in the adornment of Lansdowne House. Here he collected a splendid gallery of ancient and modern pictures, together with a library of 10,000 volumes, comprising the largest collection of pamphlets and memoirs on English history and politics possessed by any man of his time, as well as a series of MSS., which were sold to the British Museum for £5000. He was a discerning patron of genius. It was while he resided in Lansdowne House as the librarian and friend of S. that Priestley made the discovery of oxygen. Jeremy Bentham was one of his most intimate friends. S. was the patron and friend of Sir S. Romilly, and twice offered him a seat in parliament. He was also on terms of intimacy with Mirabeau, Dumont, and other foreigners of literary and political distinction. He died at his house in Berkeley Square in May 1805.

SHE'LIF, the chief river of Algeria (q. v.).

SHELL. This term is employed to designate the hard outer coverings of a large number of invertebrate animals. Shells are met with in the *Echinodermata*, in the great majority of the *Mollusca* (excluding the Molluscoids), in a few of the *Annelida*, as Serpula, Spirorbis, &c., in the *Cirropoda*, and in the *Crustacea*. The forms of the different varieties of shells are sufficiently noticed in the articles on the classes of animals to which they respectively belong; and we shall confine our remarks to the intimate structure of shell, which, until the publications of Carpenter, Rainey, and others, during the last quarter of a century, was altogether misunderstood. The doctrine formerly held, and still maintained in many popular handbooks of conchology, was, that shell is not only extravascular (or devoid of vessels), but completely inorganic, being composed of an exudation of calcareous particles (chiefly carbonate of lime) cemented together by a kind of animal glue. It is now known that shell always possesses a more or less distinct organic structure, which in some cases resembles that of the *epidermis* of the higher animals, while in others it approximates to that of the *derma*, or true skin. The nature of the organic structure is so different in the Echinodermata, Mollusca, and Crustacea, that a separate description is required for each, and as Dr Carpenter remarks: 'Even in the subordinate divisions of these groups, very characteristic diversities are frequently observable, so that, as in the case of the teeth, it is often possible to determine the family, sometimes the genus, and occasionally even the species, from the inspection of a minute fragment of a shell, as well fossil as recent.'

In the *Echinodermata*, the elementary structure of the skeleton exhibits the appearance of a network composed of calcareous and animal matter intimately united. The diameter of these apertures or meshes of network varies to a certain degree in

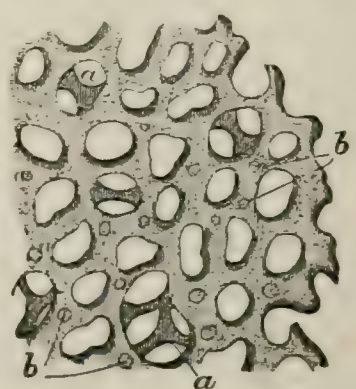

Fig. 1.—Thin Lamina of Shell of Echinus, shewing its Areolar Structure:

a, a, portions of subjacent layer; *b, b*, fractured bases of columns connecting the superposed laminæ. Magnified 164 diameters.

different parts of the same shell, the openings being larger in the inner than the outer layers, the extremes being $\frac{1}{450}$th and $\frac{1}{1250}$th of an inch. The

entire shell is made up of an immense number of such plates, which lie parallel to one another, separated by minute vertical pillars.

In the *Mollusca*, the shell is formed upon the surface of the mantle, which corresponds to the true skin of other animals. Hence it must be regarded as epidermic. It consists of cells consolidated by a deposit of calcareous salts in their interior, but, as in the case of many other tissues, the original cellular organisation often becomes so hidden by subsequent changes, as to cease to be recognisable. The typical condition of the shell in this sub-kingdom is

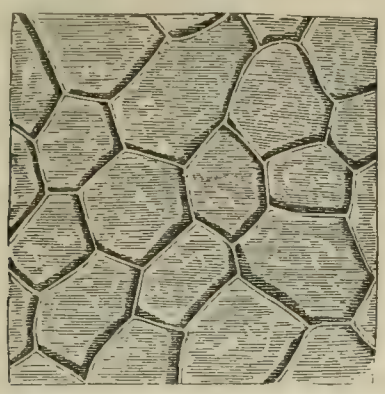

Fig. 2.—Section of the Shell of Pinna parallel to the surface, shewing Prismatic Cellular Structure, cut transversely, magnified 185 diameters.

best seen in certain bivalves—the genus *Pinna*, for example. On breaking off a small portion of the projecting margin of one of these shells, and examining it under the microscope, it is found to be made up of a vast number of prisms, hexagonal in form, and nearly uniform in size, which are arranged perpendicular to the surface of the lamina of the shell, so that the thickness of the lamina is formed by their length, and its surfaces by their extremities. On submitting such a lamina to the action of a dilute acid, the calcareous salts are dissolved, and a membrane is left which shews the prismatic structure as perfectly as it was seen in the original shell, the hexagonal divisions being evidently the walls of cells resembling those occurring in the pith or bark of a plant. It sometimes happens in recent, but more commonly in fossil shells, that the animal matter

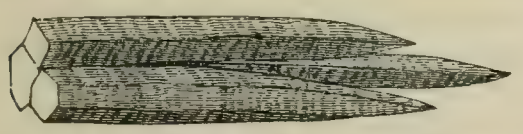

Fig. 3.—Calcareous Prisms of the Shell of Pinna, from Chalk.

decays and leaves the prisms ununited, and easily separable from one another. It is only in a few families of bivalves that the cellular structure is seen in this very distinct form, or that it makes up a large portion of the shell; and these families are closely allied to *Pinna*. In many shells, the external layer is formed on the above plan, while the internal layer is nacreous; in many, again, the nacre, or 'mother of pearl,' and in others sub-nacreous structure, constitutes nearly the whole thickness of the shell. The nacre, according to Sir D. Brewster, consists of a multitude of layers of carbonate of lime, alternating with animal membrane; and the grooved lines on which iridescent lustre depends, are due to the wearing away of the edges of the animal laminæ, while those composed of carbonate of lime stand out; it is, however, more probable, from Dr Carpenter's researches, that the peculiar lineation of the surface of nacre is due to the disposition of a single membranous layer in folds or plaits, which lie more or less obliquely to the general surface.

In the *Crustacea*, the structure of the shell has only been examined in the order of Decapods. In this order—in the common crab, for example—the

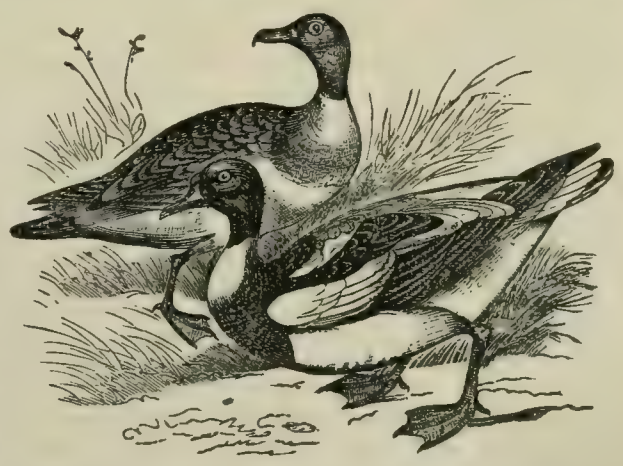

Fig. 4.—Portion of transverse section from Claw of Crab, magnified 400 diameters.

shell consists of three layers, viz. (1) an external horny epidermic membrane covering the exterior; (2) a cellular or pigmentary structure; and (3) an internal calcareous or tubular substance. The horny layer is easily detached after the shell has been for some time immersed in dilute acid; it is thin and tenacious, and presents no trace of structure. The pigmentary layer is very thin in the crab and lobster, but is much thicker in some other Decapods. The internal layer is that which constitutes the chief part of the shell; it is in this layer that the calcareous matter is chiefly deposited; but even after this has been removed, a very distinct animal basis remains, which closely resembles that which is left after the dentine of the teeth has been deprived of its inorganic constituents, as may be seen in the accompanying figure, representing a transverse section from the claw of the crab; the dark lines representing minute tubules.

For further information on this subject, the reader is referred to Dr Carpenter's various articles on the Microscopic Structure of Shells, and especially to his article 'Shell' in the *Cyclopædia of Anatomy and Physiology* (from which the materials of the present article have been almost entirely drawn), and to his *Microscope and its Revelations*.

SHE'LLDRAKE, or SHIELDRAKE (*Tadorna*), a genus of ducks of the section having the hind-toe without any pendent membrane. The shelldrakes

Shelldrake, female and male (*Tadorna vulpanser*).

are a connecting link between geese and ducks, having much resemblance to the former. The species are mostly natives of the southern hemisphere,

but the COMMON S. (*T. vulpanser* or *Bellonii*) is common on the sandy sea-shores of Britain; many coming from the north for the winter, and some remaining all the year, and breeding, making their nests in rabbit-burrows or other holes in soft soil, whence in some places the S. receives the name of *Burrow Duck*. It is a beautiful bird, the sexes nearly alike in plumage; the head and upper part of the neck green, with a collar of white, and a lower collar of rich chestnut, extending over part of the back, the rest of the back white. The whole length is fully two feet. The S. is very capable of being tamed, and breeds in domestication. Its note is a shrill whistle. Its flesh is coarse and unpalatable.—The RUDDY S. (*T. rutila*), the only other European species, is rare as a British bird, although common in many parts of Europe and Asia.

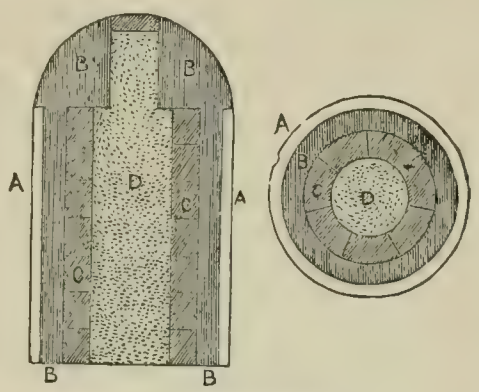
SHELLEY, PERCY BYSSHE, the eldest son of Sir Timothy Shelley, Bart., the representative of an old Sussex family, was born at Field Place, near Horsham, in that county, on August 4, 1792. His earlier education he received at home with his sisters. About the age of ten, he was sent to a school near Brentford, and thence, three years after, transferred to Eton. Shy and sensitive, yet self-willed and unsubmissive, he suffered much from the harsh discipline of masters and the tyranny of his ruder associates. In his refusal to fag at Eton, he gave early indication of that passionate impatience of every form of constituted authority not approving itself to his reason which continued through life to distinguish him, and to find expression in his writings. In 1808, he left school, and after two years passed at home, he was sent to University College, Oxford. Even thus early, he had become a free-thinker of a somewhat advanced kind, and a pamphlet, entitled *A Defence of Atheism*, which he circulated during the second year of his college course, led to his expulsion from Oxford. This so irritated his father, that for some time he declined to receive him; and on his rash marriage, in August 1811, to a Miss Harriet Westbrook, the daughter of a retired innkeeper, the estrangement between them became final and complete, the old gentleman consenting to allow his son a liberal yearly income, but never after having any intercourse with him. S.'s marriage was in its issue tragical. In 1813, a separation took place between him and his wife, who, with two children, returned to the care of her father; and three years after, the unhappy woman drowned herself. The refinements of intellectual sympathy which poets desiderate in their spouses, S. failed to find in his wife, but for a time he seems to have lived with her not unhappily; nor to the last had he any fault to allege against her, except such negative ones as might be implied in his meeting a woman he liked better. This was Mary Godwin, daughter of the celebrated William Godwin and Mary Wollstonecraft, with whom, in 1814, he travelled in France and Switzerland, and who afterwards became his second wife. Such excuse of his conduct in the matter as the theory of 'congenial souls' may afford in the eye of the moralist must to the full be allowed for S., whose later union was of almost ideal felicity and completeness. On the death of his first wife, he laid claim to his children; but this their grandfather, Mr Westbrook, strange as it may now seem, successfully resisted at law on the ground of his atheism, as exhibited in the poem of *Queen Mab*, which a year or two before he had printed, though only for private circulation. In 1815, while living at Bishopsgate, near Windsor, he wrote his *Alastor*, one of the most finished and characteristic of his works; which was followed by *The Revolt of Islam*, composed in 1817 at Marlow. During the interval, in the course of a tour in Switzerland, he had formed the acquaintance of Lord Byron, with whom afterwards in Italy he had much intimate intercourse. In March 1818, he left England finally—as it proved—to proceed to Italy; and during that and the following year, chiefly while a resident in Rome, he produced what may rank as his two finest poems—the grand lyrical drama of *Prometheus Unbound* and the tragedy of *The Cenci*. While at Venice with Lord Byron in 1820, he wrote *Julian and Maddalo*, a record in enduring verse of an interesting conversation of the discussional kind between the noble poet and himself. His other works of chief importance are: *Rosalind and Helen*, begun before he left England; *The Witch of the Atlas*, written in 1819; *Epipsychidion; Adonais* (a lament on the death of Keats); and *Hellas* (a lyrico-dramatic burst of exultation on the outbreak of the Greek war of liberty)—all three produced in 1821. The winter of 1822, S. passed at Pisa; and in the April following, he established himself near Lerici, in the Gulf of Spezia. His fondness for boating had through life amounted to a passion, and here he indulged it to the full. On July 8, 1823, in the company of an ex-naval friend, Mr Williams, he sailed from Leghorn, whither he had gone to welcome his friend, Mr Leigh Hunt, to Italy, and was lost in a sudden squall on his voyage homeward. The bodies were, after some time, washed ashore, and were burned, as the quarantine law of the country required, in presence of Lord Byron, Mr Leigh Hunt, and another intimate friend, Mr Trelawney. S.'s ashes were carefully preserved, and lie buried in the Protestant cemetery at Rome, near the grave of Keats.

In S.'s opinions, religious, social, and political, crude as they often were, and everywhere expressed with an unwise reckless vehemence, there was much that might reasonably offend; and they not only on their own account roused against him a storm of obloquy, but made him throughout life the accredited mark of the most foul and malicious slanders. To this chiefly it is to be attributed that, whilst he lived, his genius met with no wide appreciation; but since, it has been amply recognised, and perhaps no writer of his time at this day ranks higher on the whole than he. In sustained lyrical impetuosity, S. surpasses every other writer; his diction is not more remarkable for its opulence than for the expressive subtlety and precision with which it defines the nicest refinements of feeling and thought; and his page flashes with imagery like a royal robe rich with gems. But too often, whilst he dazzles, he also bewilders; he is fond of supersubtle abstractions, unsubstantial as clouds or dreams; and frequently in reading him we seem merely to be looking on wreaths of rainbow-coloured mist. This want of clear and firm outlines is more or less felt throughout all his larger works, with the single exception of *The Cenci*, in which a terrible story of real life is dramatised with consummate vigour and directness of treatment. As to the matter of the rest of his poems, they concern themselves, for the most part, not with the world as it is or has been, but with a perfected world which is to be. S. is the *vates* of the future, as Scott is the poet of the past. Of the charge of atheism against S., it is enough to say that it rests mainly on his boyish poem of *Queen Mab;* that this he did not himself give to the world; and that when, in 1821, it was surreptitiously published, he issued an express protest against his being held answerable for any opinions set forth in it. In his later works, a vague Pantheism seems indicated; and one or two passages occur which fairly admit of a purely theistic interpretation. The only complete edition of S.'s poems

is that published by Mrs Shelley in 1839. A selection from his letters, with translations and prose-essays appeared in 1840. See Medwin's *Life of Shelley* (1849); Trelawney's *Recollections of the Last Days of Shelley and Byron* (Lond. 1858); Thomas Jefferson Hogg's *Life of Shelley* (Lond., 2 vols., 1858), and the *Shelley Memorials*, by Lady Shelley (Lond., 1859).

By common testimony of all who knew him, S., who was held up to execration as a perfect monster of iniquity, was one of the purest, gentlest, most lovable of men; of the tenderest private affections, and, beyond the immediate circle of these, of the largest flowing charity. The passion of philanthropy expressed in his writings found as practical an expression in his daily life as if he had never made any very great profession of it. The episode of his first marriage seems more or less awkward for him; but the one passionate frailty of a boy can scarcely be held a serious blemish on a man whose whole subsequent life was exceptional in virtue and beneficence.

Mary Wollstonecraft Godwin, wife of the poet, was born in London 1798, married Shelley, as above stated, in 1816; and in the same year produced a remarkable novel, entitled *Frankenstein*, the hero of which, a profound student of nature, discovers the secret of creating life, and produces a monster whose history, though wild and horrible in its incidents, is invested with a strong human interest. The work had a great success, and may be reckoned the best of Mrs Shelley's literary efforts. Other novels of hers are *Valperga*, *The Last Man*, *Lodore*, and *The Fortunes of Perkin Warbeck*. She likewise wrote *Rambles in Germany and Italy;* a series of biographies of foreign artists and poets for the *Cabinet Cyclopædia;* and carefully edited her husband's poems. She died in London, February 1, 1851.



SHELL-GUN belongs rather to the past than the present, as in modern rifled artillery all guns fire shells. Before their introduction, however, shells were fired from guns of large bore, and proportionately small thicknesses of metal, not differing materially from howitzers, except that they had greater length.

SHELL-LAC. See Lac.

SHELLS, called in earlier times bombs, consist of hollow vessels of metal, containing gunpowder or other explosive compound, so arranged that it shall explode at a certain point, and spread destruction around by the forcible dispersion of its fragments. The invention of this murderous missile cannot be accurately traced. Shells were employed in 1480 A. D. by the sultan of Gujerat, and by the Turks at the siege of Rhodes, in 1522. The Spaniards and Dutch both used them during the war of Dutch independence; and they appear to have been generally adopted by about 1634. As shells required Mortars (q. v.) for their projection, they were not used in naval warfare until the French constructed special bomb-vessels in 1681; but since that period, shell-guns, being cannon of large bore, have been introduced, and shells are now employed by all ships of war.

Until within a few years, every shell was a hollow sphere of cast-iron, varying in thickness from half an inch to two inches, and in diameter from five and a half inches to thirteen inches. The sphere had a fuse-hole (like a bung-hole) an inch across, through which the charge was inserted, consisting of pieces of metal and powder to burst the shell. The hole was plugged by a fuse, which was a tube of slow-burning powder, timed to communicate fire to the charge after the lapse of a certain number of seconds. This fuse might either be kindled by hand the moment before the mortar was fired, or its ignition might be effected by the act of firing itself. The Shrapnell shell, introduced by Colonel Shrapnell of the Royal Artillery about 1808, contained a number of bullets, and being fired at bodies of men, it was timed to explode about 100 yards before reaching them, when the shell burst, and the bullets with the fragments continued their course, diverging continually as they went, until they reached their object in a death-cloud. The *Concussion shell*, or *Percussion shell*, is one in which the charge is fired by the detonation of a cap on striking an object. If sufficiently delicate to explode on touching a soft object, and at the same time not to be exploded by the resistance of the air to its rapid flight, this form of shell is the most certain in execution.

Since the introduction of rifled ordnance, the shell has become the commonest form of projectile. It has ceased to be spherical, and is usually in the shape of an elongated bolt. Several rival shells at present divide public favour, and compete for adoption into war service. Without noticing the numerous varieties which are in course of trial on the continent and in America, the following are the principal British competitors. The *Armstrong* shell is a pointed bolt of iron (usually percussion), containing an inner 'segment shell,' made

Armstrong Shell:

A, lead casing; B, outer shell; C, segments; D, charge.

up of 49 segments of cast iron. Seven of these segments form a circle, or ring, and seven circles give the necessary length. A coating of lead affords a soft medium for fitting into the grooves of the gun. The shell thus made somewhat resembles a bottle without the neck. The necessary bursting charge having been inserted, the rear-end is plugged with lead, the fuse is screwed into the front, and the shell is ready for action. This projectile has a great and accurate range, and its segments cannot fail, on explosion, to do great damage. The principal drawback has been found in the lead-casing, which is often thrown off in parts soon after the shell leaves the gun, and which thus falls among the foremost ranks of the army using it, sometimes inflicting severe wounds. The *Whitworth* shell is an elongated hexagonal bolt of iron or steel, cast in one piece, and with a bursting charge at the rear-end. It explodes on percussion; but the space allowed for the burster is deemed insufficient to produce the full effect which the length and correctness of the weapon's range give cause to expect. The *Lancaster* shell is oval, to fit the

Whitworth Shell.

bore of the *Lancaster* gun (q. v.). There are many other forms, but they differ principally in the devices used for making the shell conform to the rifling of the gun. *Martin's* shell must, however, be noticed, from its peculiarity of being charged with molten iron, which sets on fire all combustible matter on which it can be thrown. The *Diaphragm* shell, invented by Colonel Boxer, R.A., has an iron division or diaphragm to separate the powder in the shell from any balls or slugs, in order that the friction of the latter may not prematurely cause the powder to explode. A six-pounder diaphragm shell contains 30 carbine-balls; an eight-inch shell, 322 musket-balls.

SHELL-SAND. Sand consisting in great part of fragments of shells, and often containing a small proportion of organic matter, is a very useful manure, particularly for clay soils, heavy loams, and newly-reclaimed bogs. It is also advantageously applied to any soil deficient in lime. It neutralises the organic acids which abound in peat, and forms with them compounds which serve as food for plants. Great deposits of shell-sand are found on the coasts of Devonshire and Cornwall, and are of great value in the agriculture of that district. Shell-sand is also found on many other parts of the British coast, and nowhere more abundantly than in the Outer Hebrides. The sand of many parts of the coast, however, being mostly silicious, is incapable of the same use. Shell-sand is much used as a manure in some of the maritime districts of France, as Bretagne and Normandy.

SHEMA'KHA, a maritime government of Transcaucasia, Russia, bounded on the S. by the river Kur, and on the N. by the Caucasus. Area, 21,654 sq. m.; pop. 633,886. North of the Kur and around its mouth the surface is level, low, and fruitful, and there are numerous warm and fertile valleys, though little of the surface is under cultivation. Only in the towns and seaports, and in the villages in their vicinity, are agriculture and industry pursued. The mountainous regions are inhabited by a rude predatory population.

SHEMAKHA, the capital of the government of the same name, about 70 miles west-north-west of Baku. It is a thriving town, carries on extensive manufactures of silk and cotton goods, and is much engaged in horticulture and in general trade. Pop. 22,014.

SHEMI'TIC (Semitic*) **LANGUAGES**, the general name of a certain number of dialects, supposed at one time to have been spoken by the descendants of Shem. The term is of recent origin (Schlözer, Eichhorn), and a misnomer; for, in the first place, not all the nations derived in Genesis from Shem spoke an idiom akin to those understood by the term Shemitic (e. g., the Elamites, Lud, &c.), and, on the other hand, Canaan and Cush, whose Shemitic speech is undoubted, are there traced to Ham. Shemitic Languages, however, as a 'conventional appellation,' is still the best of all the general terms hitherto proposed (Arabic; Syro-Arabic, analogous to Indo-Germanic).

The family of Shemitic languages, which spread originally over Canaan (Phœnicia and Palestine), Assyria, Aram (Syria, Mesopotamia, Babylonia), and Arabia; and, at a later period, over part of Asia Minor and the Punic northern coast—i. e., from the countries on the Mediterranean to the Tigris, and from the Armenian Mountains to the south coast of Arabia—may broadly be divided into three principal classes: 1. The Aramaic or Northern (north-eastern) dialect, comprising, chiefly, the so-called Chaldee and Syriac; 2. The Southern, the chief representative of which is the Arabic, closely allied to whose older (Himyaritic) form is the Ethiopic; 3. The Middle, or principally Hebraic, to which also belong the languages of the other Palestinian inhabitants, those of the Canaanites and Phœnicians above all. The difference between the Middle and Northern branches, is less sharply marked, than between the Middle and the Southern or Arabic.

Before proceeding to treat of them individually, we shall try to point out their general position among other languages, and principally, the salient points of difference between the Shemitic and that other most important family of the Indo-Germanic or Aryan languages. First of all, then, we notice the preponderance given in Shemitic to the consonants in contradistinction to the vowels. The former are indeed the basis and the body of its words. The vowels are more or less accessories, modifying, fixing, precising the meaning, but never themselves containing it, while in the Indo-Germanic languages the root itself consists generally of a combination of vowels and consonants. A further peculiarity is the prevailing 'triliteralness' of Shemitic roots in the advanced stage in which we now know them. The Indo-Germanic languages derive their wealth from the logical law of their composition of roots, of verbs, and particles; the Shemitic add to their store in phonetically multiplying their sounds: either by splitting, as it were, their single consonants into two or more, through the reduplication of radicals, or by the addition of new consonants to the primary root, which is thus developed often from a monosyllabic (for by far the greatest number of Shemitic roots consisted primarily of two consonants only, to which a third was generally added at a later period) into a root of five letters. Compound words are of the utmost rarity both in the noun (except proper names) and the verb, and they never consist of combined roots of verbs and particles, but of verbal and nominal roots. Regarding the formation of cases, tenses, and all those other grammatical changes of noun and verb which, in the Indo-Germanic family, are wrought—as far as the verb or noun itself is concerned—almost exclusively by suffixes, while the radical vowel changes merely according to euphonic rules within its own limited sphere; the Shemitic languages, principally and chiefly work their flexions by a change of vowels within the radical consonants, leaving the latter themselves intact. Only when these changes suffice no longer for the more elaborate modes of speech and thought, supplementary letters and syllables are sought in aid, and a certain small number of prefixes or affixes represents the vast and varied groups of little words (amounting at times to whole phrases) of the Indo-Germanic. The Shemitic languages are also, if poorer, less complicated in forms than the former family. There are only two genders—which, however, are also distinguished in the second and third persons of the verb—and two principal tenses. These are strongly marked by the position of the personal pronoun, represented by a suffix in the so-called perfect and by a prefix in the so-called aorist or imperfect (future). The former expresses the finite, the completed action, the fact; the latter, the incompleted action, the thought, that which is becoming, growing, as it were, into a fact. One of the most curious features

* In Hebrew, the name from which the adjective is derived, is spelt *Shem;* but, as in many other cases, the *sh* of the original was transformed by the Septuagint into *s* (see SHIBBOLETH); and hence, through the influence of the modern versions that have in this respect followed the Septuagint, the form *Semitic* is more current among continental writers than *Shemitic.*

is the sudden change that may be produced in the two by a certain prefixed conjunctive-consonant. Perfect then becomes future, and *vice versa*. Declension, in the Indo-Germanic sense, exists, if at all, in an extremely limited sense in Shemitic. The juxtaposition of two words (with slight vowel-changes) forms the genitive, while the other cases (in the Hebraic at least) are formed by prepositions. The oblique cases of pronouns are indicated by suffixes. The syntax is of the crudest and simplest description: a mere stringing together of sentences without any particular attempt at a logical and methodical arrangement of periods, according to their temporary superior or inferior relation to the subject-matter.

Another most important point of distinction between the two families is formed by what has been called their lexical difference, i. e., the want—except in a few isolated cases—of any correspondence or identity in their individual words. Most of those words which exhibit a similarity, can be shewn to have been either adopted at a late period, or they simply fall under the category of onomatopoeic words (words imitating the sound of the object expressed, and therefore shewing in all cases greater or smaller affinity to the original sound); or, again, words in which the common type of human language would involuntarily, and under all circumstances, connect a special meaning with a special sound, and would, therefore, be more or less identical in all idioms. Of words introduced into European languages by Shemitic (Phœnician) traders may be instanced, *kanua* = cane, *gamal* = camel, *mor* = myrrh, *kezish* = cassia, *ahelim* = aloe, *nerd* = nard, *carkon* = crocus, *sappir* = sapphire, *sak* = sack, &c. Of onomatopoeic terms, *lakak* = (Sansc. *lih*) to lick, *charat* (Sansc. *charîdan*) = to grate, scratch, *galal* = to roll, *parak* = to break, &c. On the other hand, words have crept into Shemitic from foreign languages; e. g., the Egyptian, *ior*, *iero*, *iaro*, river, Nile, is found as *yeor* in Hebrew, *pardes* (Heb.) paradise, is Persian, *kop* (Sansc. *kapi*) is the Heb. for ape, *karpas* (Sansc. *karpâsa*) = wool, cotton, &c.

As regards the age of the family of Shemitic languages, it is matter of great doubt whether or not they were developed earlier than any other, e. g., the Indo-Germanic. The monuments that have survived are not sufficient for us to form a final judgment as yet. It stands to reason, however, that a development may have taken place simultaneously and independently in the idioms of other nations. The notion long cherished (and still upheld by a few isolated speculators) that Hebrew was the original language of all mankind up to the episode of the tower of Babel, may here be passed over without remark. See PHILOLOGY.

We shall now endeavour to draw an outline of the relation of the Shemitic languages among themselves, and to cast a rapid glance at their individual characteristics and history, referring for fuller details to the articles devoted to the special branches indicated. Although the Shemitic languages are clearly sister dialects, their relationship is far from being so close as, for instance, that of the different Greek dialects. Thus Abraham, belonging by his descent to a people of Shemitic tongue, and coming from a country where Shemitic was the general language, at his arrival in his new place of abode, inhabited by Shemites, was considered, and considered himself a foreigner to a much greater extent than it would have been the case had a Greek emigrated from one part of Greece into another. It would be more fit perhaps to institute a comparison between the different Shemitic dialects and the Germanic languages among themselves: German, Dutch, Danish, Swedish, Norwegian, &c.; or the Slavonic idioms: Lithuanian, Lettish, Russian, Polish, Bohemian. But even these are not so far removed from each other as the Shemitic idioms. What the latter have in common are those grammatical and other characteristics indicated above and the *root-words* themselves, which nearly everywhere have the same original signification; only that in this respect the Arabic shews by far the largest development of meanings out of the single roots, and consequently an unparalleled wealth of derivatives. Yet it must not be forgotten that our relics of ancient Hebrew are of a scanty nature, and that the Arabic has remained a living language until our day, and has, through Islam, spread further than any ancient and perhaps even modern language.

Regarding the much-vexed question as to which of the Shemitic languages is the oldest, it must be confessed that no positive result has yet been attained. For although the oldest palpable monuments of Shemitic have survived in Hebrew, while our earliest documents in Aramaic date from Cyrus, and those in Arabic, even centuries after Christ (Himyaritic, Ethiopic, 4th c.; northern Arabic, 6th c. A.D.), yet we cannot now decide which of these has preserved the type of the original mother-tongue most intact. It sometimes happens that vast internal movements, or a series of events in the history of a people—wanderings, wars, and the like—change, quicken, and develop its language even to decay, before it has had time to beget a literature. When this time does arrive, we meet already with all the traces of this decay in imperfections, corruptions, and archaisms of form. Thus, the Hebrew of the Bible, that is the most ancient form in which it has survived, offers more grammatical analogies (in incomplete structure, inflexion, &c.) to the modern than to the ancient Arabic, which lasted in its primitive purity and fulness of form as long as the simple life of the dwellers in the desert was not broken by those events which upheaved, from the time of Mohammed, their whole existence, and brought them in closest and most violent contact with other nations of other tongues. Then that process of decomposition, or phase of negligence and corruption, set in, which resulted in the looseness exhibited by modern Arabic. It thus reached the downward stage of the Hebrew of the Old Testament at ever so much later a period. Arabic classical literature thus exhibits, compared with the Hebrew, and even more with the Aramaic—which we meet in a worse state of aged and crippled organism and stunted form—about the same vigour, freshness, and fulness of form and structure, which the Sanscrit exhibits among the Indo-Germanic or the Gothic in the narrower circle of the Germanic dialects. With all this, however, we cannot absolutely decide in favour of the Arabic as the nearest approach to the original type. The phase in which it enters into our historical horizon may be as far if not further removed from it even as the Aramaic. Its hasty individual development may have quickened more radical changes than even the decaying or decayed other branches present. So that, as we said, for the present at least, the question of priority must remain open. We shall, however, allot the first place to the second or Southern Shemitic (Arabic) class, simply because of its copiousness of words and development of forms. A faint trace of its peculiarity of article (*al*) is supposed to be found in Gen. x. 26 (*Almodad*); but this seems fallacious enough, considering that the Hebrew article must have been originally the same, and the word may simply exhibit the ancient Hebrew form. In the golden epoch of Hebrew literature, Arab culture does indeed seem to have stood in high renown—

Solomon's wisdom is likened unto that of the Arabs, Queen Sheba is an Arab queen, and Job's friends are Arabs. On its peculiar history and development, however, we cannot here dwell. (See ARABIAN LANGUAGE and LITERATURE.) Suffice it to observe generally, that Arabic is not only the richest of Shemitic, but one of the richest of all languages, with its more than 6000 word-roots, and about 60,000 words; while the Hebrew has about 2000 of the former and 6000 of the latter. The 22 consonants of the Aramæans, and the 23 of the Hebrews, have been augmented into 28 with the Arabs. They further have twice the number of the Hebrew regular conjugations, in which, again, the latter exceed the Aramaic by one. The same abundance is noticeable in the Arabic tenses, declensions, &c. The general wealth of this language, however, will be best appreciated by its possessing some thousand different terms for a sword, and a proportionate number of words for lion, serpent, and the like; while on the other hand, its adaptibility and versatility are shewn by one word often possessing a vast number of meanings. Anciently, it had two principal branches: the Himyaritic, spoken in the south, which has perished almost completely (a few partly mutilated inscriptions, recently brought to the British Museum, were published some years ago, and their interpretation has been attempted by Osiander and Levy in the *Germ. Or. Society's Transactions*), and the Koreishite, which, being the idiom of Mohammed's tribe, became *the* paramount Arabic for all times. The Ethiopic (see ETHIOPIA) is by some investigators held to have flowed from the Himyaritic; but from the 14th c., the Amharic dialect (also Shemitic, but with little capacity for writing purposes) has superseded the Ethiopic almost completely.

The North Shemitic or Aramaic, to which we now turn, is the language of the whole district between the Mediterranean and the Tigris, south of the Taurus, north of Phœnicia, the Israelitish territory, and Arabia. Here we have again to distinguish between Syria Proper, Mesopotamia (between Euphrates and Tigris), and Babylonia (south of Mesopotamia), whither the Israelites were carried by Nebuchadnezzar. Yet, with respect to this latter country, it can hardly be doubted that another dialect besides the Aramaic was spoken in it. But whether this was 'Medo-Persian,' ('like the Assyrian'), or some other 'Turanic' idiom, largely mixed with Shemitic ingredients, must remain doubtful until our knowledge of 'Turanian' and our reading of cuneiforms shall have advanced somewhat further. There is, however, but one voice among competent investigators, that whatever strange elements the Babylonian and Assyrian languages may contain, they have a full claim to be reckoned among the Shemitic. The Aramaic in general is, as has been observed before, poorer than the Hebrew in grammatical forms, vowels, &c., besides having a peculiar tendency to blunting its consonants, changing its soft *s* into *d*, *ts* into *t*, *sh* into *th*, and the like. It further does not express its article by a prefix, but by an *Alef*, and it forms its passives, not by a change of vowels, but by a special syllable prefixed to the root. The first distinct trace of a difference between Hebrew and Aramaic is found in Gen. xxxi. 47, where it is found necessary to translate Laban's designation of the stone-heap erected in memory of his peace with Jacob. Although the ancient Babylonians had, in all probability, a rich and important literature; yet nothing of it has survived. The so-called Babylonian fragments supposed to have come down in Arabic translations are a mere fiction. All the Aramaic literature which we now possess is derived from the Jews, and of a very late date. The Babylonian exiles, both those who returned to Palestine and those who stayed in the land of their captivity, made Aramaic their habitual language. It was the common tongue of Palestine at the time of Christ, the Hebrew being then chiefly the 'holy language'—i. e., the language of temple and synagogue. Thus, the Shemitic words used in the New Testament are one and all Aramaic (Mammon; Raka; Eli, Eli, &c.; Talitha Kumi; Abba; &c.), and the same may be said of the Shemitic terms found in Josephus. The oldest remains in this idiom (variously called Hebraisti, Arami, Sursi, Chaldee) are certain portions of the Old Testament (Daniel, Ezra, &c.), the Targums (q. v.), the Mishna (to a certain extent, at least), the Talmuds, and the Midrashim. Idiomatic shades are again observable in these different documents; but while, as a living language, it was spoken and pronounced differently in the different districts of Palestine and Babylon, yet the special subdivisions into special provincial dialects which have been attempted can hardly be said to be correct. From the 2d c. A.D., Christian writers, chiefly in Mesopotamia, Edessa, Carrhæ, Nisibis, began to use this language in their writings, which are principally theological (Translation of the Bible) and dogmatical, but which also treat of medicine, history, philosophy, mathematics, &c. Yet their Aramaic assumed a character so essentially different, that, in some respects at least, it became an entirely distinct dialect, viz., Syriac, which, at a later period, assumed also—to make the breach complete—an alphabet of its own (Estrangelo). Many have been the attempts to account for this strange difference (the very existence of which was, on the other hand, almost totally denied at one time), but with no satisfactory result. Certain it is that the mere geographical reasons (East and West Aramaic, &c.) do not hold good, and are arbitrary and fallacious. The Syriac, as a living language, ceased to be spoken since the 10th c., and only a few Syrian Christians in Kurdistan and Mesopotamia are supposed to use a kind of vulgar Aramaic. Syriac literature ceased about three centuries later. As the language of the church, however, it is still in use with the Jakobite, Nestorian, and Maronite branches of the Syrian church. Minor sister dialects of Aramaic are the Samaritan, a corrupt Judæo-Aramaic mixed with Arabic words; the Zabian or Nazaræan (Mandaic), the language of a theosophical sect ('disciples of John the Baptist') standing between the Syriac and Chaldee, and mixed with Persian, but bearing altogether the stamp of an uncouth, ungrammatical, sadly-neglected idiom; further, the Palmyrene (Palmyra), which, with a written character closely akin to the square Hebrew, offers but little variations from the Syriac; and finally, the Ægypto-Aramaic, which is found on a few monuments (Stone of Carpentras, Papyri), and probably belongs to Jews, who, at a late period, had immigrated into Egypt, and had adopted the Egyptian religion. Its words are principaliy Judæo-Aramaic, but with a large infusion of foreign elements.

The third principal branch, the Middle Shemitic, which comprises Hebrew and Phœnician (Punic)—and all the questions connected with these—have been discussed at some length under JEWS and PHŒNICIA; to which we refer. See also the special articles ARABIC, CHALDEE, ARAMAIC, &c.

SHEMITIC NATIONS or SHEMITES. The different nations generally comprised under this name, viz., the Assyrians, tLe Chaldæans or Babylonians, the Syrians, Phœnicians, Hebrews, Arabs, and Ethiopians, are all treated specially in the

course of this work; it only remains here to add a few observations on the characteristics ascribed to them all in common, and on the influence they have exercised upon the history and development of humanity. As regards the language, the poverty of the inflections, the well-nigh absolute impossibility of expressing abstract ideas, the general absence of compound verbs and substantives, and the primitive state of the syntax in the Shemitic, as contrasted with the wealth and vigour of the Aryan, have been noticed in the previous article. From this arises, as an almost natural consequence, the general inferiority of Shemitic literature—to what we emphatically call 'classical literature.' Certain most important forms of Indo-Germanic poetry, for instance, are completely wanting in the Shemitic, such as the epopee and the drama; although, on the other hand, the peculiar ancient form of Arabic poetry—the Kasida—and the grand bursts of pathos found in the religious books of the Hebrews, are vainly sought in Indo-European literature. Again, a primitive state of Law seems to have developed among the Aryan nations, the chief characteristic of which was a recognition, albeit a dim enough one, of individual rights, in as far as they did not war against the complex unity of the 'State.' With the Shemites, in the absence of that talent for organisation and conciliation which is so essential a mark of the Indo-Europeans, we find either a patriarchal, an anarchical or a despotical kind of government. Science and philosophy, in the larger sense of the word, are the almost exclusive property of the Aryans. The inferiority of the Shemites in these respects, however, is amply counterbalanced by the sublime place they take as the ethical teachers of all humanity. How the hard and narrow egotism which, not quite unjustly, is ascribed to them, ever came to bear and ripen those grand moral maxims with which we meet in the earliest Jewish records, and which, wrought up to their purest idealism, form the shining glory of the New Testament, is a problem of which some seek the solution in a peculiar *intensity* of character inherent in the Shemitic races; while others account for it by direct 'Inspiration.' The same may be said of that Monotheism which belonged, in the first instance, to the Hebrews out of all the nations of the earth. It is a grave mistake, however, to describe, as Renan does, the Shemites indiscriminately as monotheists. Babylon and Assyria, and Syria or Phœnicia, and the ante-islamic Arabs, were neither more nor less polytheistic than the early or present inhabitants of India. And, we may well add, not before the return from the Babylonian exile are the Jews themselves, as a body, to be considered as real monotheists. But ever since, both they, and, from the time of Mohammed, the Arabs, have been the representatives of a more austere and exclusive dogma of the unity of the godhead, than a great part of the civilised world has found good to accept up to this day. Both Christianity and Islam, the most powerful religious agents, the one for nearly two thousand years, the other for about twelve hundred, are in their origin Shemitic, and their influence need not here be enlarged upon. For what we owe to the Shemites in the field of industry and inventions, and the civilisation these carried with them wherever they were imported, we need only refer to PHŒNICIA. Nor ought we to forget that the very Alphabet itself is of Shemitic origin.

SHEMITIC PLURAL. The Shemitic languages, particularly the Hebrew, often use the plural where other languages only make use of the singular. This is particularly the case in terms of space and time—their vastness being conceived, so to say, as a multiplicity. Thus, certain regions, like Heaven —which, through the influence of the Bible language, is also with us sometimes used *pluraliter*— —the expanse of water; further, the place at a person's head or feet, or even certain limbs of the body (conceived as space), like neck, face, &c.; or, again, periods of times, like youth, age, life, and special *lasting* qualities or states, like barrenness, blindness, mercifulness, and the like, are put in plural number, where we have the singular only. It is further applied to might and strength, as consisting originally of a multiplicity of elements of power. This is particularly shewn in the word ELOHIM (q. v.), = a Unity of many 'Mights'—i. e., the Supreme Being. The false conclusions as to the plurality of the Divine Persons being proved by this word are best refuted by the occurrence of the plural in the word Master (Adon), Lord (Baal), when these stand unmistakably for a single human individual, and are meant to express merely his proprietorship of some object or other.

SHENANDO'AH, a river of Virginia, U.S., the largest tributary to the Potomac, drains the beautiful and fertile valley between the Blue Ridge and the principal range of the Alleghanies. It rises in two branches near the centre of the state, and runs north-east to the Potomac, 170 miles, being navigable for small boats 100 miles. In the war of 1861—1865, this valley was the scene of numerous conflicts, was successively occupied by the opposing armies, and finally laid waste by General Sheridan in the autumn of 1864.

SHE'NDY, a town of Africa, in Lower Nubia, on the right bank of the Nile, 100 miles in direct line below Khartoum. At its markets, two of which take place every week, a large variety of articles, as wheat, straw, salt, and cotton goods, are sold. Near the town, which gives name to a large district, the finest senna is obtained. Pop. about 10,000.

SHENSTONE, WILLIAM, the son of Thomas Shenstone of the Leasowes, Hales Owen, Shropshire, and his wife Anne Penn, was born there in the year 1714. In 1732, he was sent to Pembroke College, Oxford. Whilst there, he devoted himself much to the study of English poetry, and in 1737 he published without his name a small volume of miscellaneous verse. Subsequently, for some years, he lived in a somewhat vagrant way, yet without ceasing to cultivate his talent. In 1741, appeared his *Judgment of Hercules;* and next year, *The Schoolmistress*, the work by which chiefly he continues to be remembered. In 1745, his parents being dead, he established himself on his property of the Leasowes, where he thenceforth continued to reside. He busied himself with landscape gardening, and such was his success in beautifying his little estate, that it attracted visitors from all quarters, and brought him more fame than his poetry. He was thus, however, led into serious pecuniary embarrassments, from which, on February 11, 1763, a putrid fever relieved him.

The Schoolmistress, which has secured for its author a permanent if humble place among English poets, is written in the stanza and antique manner of Spenser's *Faery Queen;* and in the contrast between the stateliness of the vehicle, and the familiar and homely quality of the subject, with the graphic truth of its treatment, there is a singular source of charm. The other works of S. are for the most part quite insignificant; but his *Pastoral Ballad* has touches of exquisite tenderness and truth of sentiment expressed in a simple and appropriate melody.

SHEOL (LXX. *Hades, Thanatos*, Vulg. *Inferi*), a Hebrew term of very frequent occurrence (65

times) in the Old Testament, and rendered by the Authorised Version: grave, hell, or pit. Its derivation is doubtful: while some connect it with a root, denoting to seek, others derive it from a root, 'to dig out,' 'to hollow' (compare Germ. *Hölle*). The use of the word in the original would seem to prove a great fluctuation of the dogma respecting the world to come, during the various periods represented in the special parts of the Bible. Sometimes it does stand unmistakably for 'tomb,' although our notions of an artificially prepared grave do not originally belong to it; at other times, it is the abode of disembodied spirits, whether good or evil. It is the place where the dead go to be united with their 'people,' their 'ancestors,' friends, and all the departed. It was placed in the centre of the earth, or below the ocean, and was a dismal, dark place, like the Orcus, or Tartarus. It has gates and bars, it has chambers, valleys, and rivers, and its inhabitants—the shadows—(*Rephaim* = feeble ones), who ordinarily enjoy deep repose in this 'reign of silence,' are troubled by being called up to the surface, or tremble at the arrival of some great tyrant. As the receptacle of all things, it contains the shadows even of trees and kingdoms. It is described as all-devouring, remorseless, and insatiable. There can be no doubt of the existence of an idea—however vague—if not of immortality, in the modern sense, yet of some state after life among the Hebrews, even in the earliest times. For the Gehenna (Ge-Hinom) of the New Testament—the contemporaneous Sheol—see HELL.

SHEPHERD'S DOG, or SHEEP-DOG, the most useful and valuable of all kinds of dog, and universally employed by shepherds throughout Europe, and in the countries colonised from Europe, and also in some parts of Asia, to assist them in the tending of their flocks. Without it, the shepherd would be utterly incapable of taking care of the great number of sheep often under his charge; and the expense of keeping the requisite number of shepherds would far more than take away the profits of sheep-farming. That the dog was employed in the tending of sheep in very ancient times, we learn from the allusion to the *dogs of the flock* in Job xxx. 1. Buffon imagined the shepherd's dog to be the original of all the domesticated dogs; but was unable to assign any good reason for such an opinion. The shepherd's dog exhibits nearly the same characters in all parts of Europe, although there are slight diversities in different countries, as between that of England and that of Scotland, there known as the *Collie*. It is of middling size—differences of size, however, being amongst the characteristics of different races; of rather slender form, with a pretty sharp muzzle; the ears erect, or, in some races, drooping at the tip; the hair soft, long, shaggy, and somewhat waved; the tail slightly pendulous, more or less recurved, and very bushy; the feet well protected by hair, so as to be adapted for rough ground. The eye is very bright and intelligent, although the ordinary demeanour of the animal is remarkably calm and quiet. No kind of dog is more intelligent, and perhaps none so docile. Its ready comprehension of the meaning of its master, its prompt obedience to his word or gesture, its evident knowledge of what is requisite to be done, and the services which it performs, can never be observed without admiration. A shepherd's dog exhibits the utmost care to prevent sheep from straying off the road along which they are being driven, and sets itself, often of its own accord, to watch any gate or gap in the fence, or goes immediately to bring back stragglers. It is equally useful on the bleak moor or wild mountain, readily going for sheep, and bringing them from a distance. The sheep become perfectly acquainted with it, and evidently regard it as a friend, and not as an enemy, although the appearance of any other dog would alarm them at once. It knows the sheep of the flock it is required to attend, and even in a crowded market adroitly separates them from others with which they have become mingled. Its remembrance of places is obviously very accurate; and a dog which

Shepherd's Dog, or Collie.

has found great difficulty in conducting sheep through crowded thoroughfares, does the same work much better on subsequent occasions. The intelligence of the shepherd's dog has sometimes been proved in a very remarkable way by dishonest masters employing them to steal sheep; the master merely indicating by some sign the sheep which he wished to add to his own flock, and leaving the dog to do it in his absence. For stealing sheep in this way, a farmer in the south of Scotland was hanged about the end of last century. More frequent instances are on record of the shepherd's dog conducting a flock of sheep safely home for many miles, unaccompanied by the shepherd. The shepherd's dog is affectionate, and becomes strongly attached to its master, but is generally shy to strangers. It is generally treated with great gentleness by the shepherd; no severity is used in its training, nor could be used with advantage. It is very muscular and active, and capable, perhaps beyond any other kind of dog, of continuing its exertions during a long time.

The shepherd's dog is often crossed with other kinds of dog, and particularly with the pointer and setter. Dogs are thus obtained, which, whilst capable of all the services required by the shepherd, are equally capable of being employed in the pursuit of game, and are most successful in night-poaching.

The *Drover's Dog* is very often a cross between the shepherd's dog and the mastiff, the foxhound, the pointer, or the grayhound. It displays many of the best qualities of the shepherd's dog, and if too frequently very different from it in its cruel treatment of sheep, the fault is originally that of the brutal master.

SHEPHERD'S PURSE (*Capsella*—formerly *Thlaspi—Bursa Pastoris*), an annual plant of the natural order *Cruciferæ*, a very abundant weed in gardens and cornfields in N. America, and remarkable as one of the few plants that are found over almost the whole world, adapting themselves to almost all soils and climates. It is a very variable plant, from 3 inches to 2 feet in height, with root-leaves more or less pinnatifid, all the leaves more or less toothed, and rough with hairs. The root-leaves spread closely along the ground. The flowers are white and diminutive. The pouch, from which the English name

seems to be derived, is laterally compressed, and somewhat heart-shaped. This is a troublesome weed where it abounds, but being an annual, it is extirpated by continual and careful cultivation.

SHE'PPEY, Isle of, a portion of the county of Kent, insulated from the mainland by the Swale, an arm of the estuary of the Medway, is nine miles long, and four miles broad. In early times, its dimensions were much greater, but the sea has encroached upon, and is gradually eating away, the northern shore, which is lined by cliffs of London clay, from 60 to 80 feet in height. The church of Minster, formerly in the middle of the island, is now on the north coast. Great numbers of interesting fossils are found embedded in the London clay, of which the whole island is composed. In the north of the island, corn is grown, but the south districts, which are low, are laid out in grass. Almost the whole of the inhabitants are massed in the seaport of Sheerness (q. v.).

SHE'PTON MA'LLET, a market-town of Somersetshire, five miles east-south-east of Wells. It is a town of considerable antiquity, and is mentioned in *Domesday Book* as Sepeton. Its grammar-school, free to twelve boys, was founded in 1627. Worsted stockings, crape, serge, and velvets are manufactured. It contains several large breweries. Pop. (1861) 4868.

SHE'RBET, an oriental beverage, much used in Mohammedan countries, where stimulating drinks are forbidden. It consists of the juices of various fruits diluted with water, and sweetened exactly in the way in which lemonade is made in Europe.

SHE'RBORNE, a market-town of Dorsetshire, on the river Yeo, 18 miles north-north-west of Dorchester. The King's School, founded in 1550, has an endowment of nearly £1000 a year, and several exhibitions of £40, tenable for four years at either of the great English universities. There are several silk-throwing mills. Pop. (1861) 5793.

S. was the Saxon Scireburn (*scir burna*, clear brook). It was erected into a bishopric in 705, and remained the seat of a bishop till 1075 or 1076, when the see was removed to Old Sarum. It was a prosperous place, and the seat of considerable cloth-manufactures in the time of Leland and Camden.

SHERIDAN, Richard Brinsley, was the son of Thomas Sheridan, a lecturer on oratory and elocution, in his day of some notoriety. He was born at Dublin in September 1751, in due course was sent to school there, and afterwards removed to Harrow. He gave no promise as a boy of the brilliancy he afterwards displayed as a man, being pronounced a hopeless dunce by all his teachers. He does not seem to have been brought up to any regular employment; and after his elopement and marriage in 1773 with a Miss Linley, a public singer of great beauty and accomplishment, his prospects did not seem bright, more especially as he insisted, on a point of pride, that his wife should give up her profession. As the readiest resource he betook himself to literature. The lighter drama was the sphere which attracted him, and in January 1775, his first comedy, *The Rivals*, was produced. Damned on its first appearance, through certain deficiencies in the acting, this piece on its repetition found gradually the favour with the public which its wit and vivacity deserved, and made the reputation of the writer. In the course of the year following, S. followed up his success by a farce of no very great merit, entitled *St Patrick's Day, or the Scheming Lieutenant*, and a second comedy, *The Duenna*, amid the sparkling dialogue of which are interspersed some songs of exquisite merit. He now became in some unexplained manner —for though his pieces were most successful, they could scarcely have brought him the necessary funds—part proprietor of the Drury Lane Theatre; and in 1777, his *School for Scandal* was produced there. This, which is by much his greatest effort, instantly leaped into the popularity it has ever since continued to retain. His other works for the stage were the inimitably clever farce, *The Critic* (1779), and, after a long interval, *The Stranger* and *Pizarro* (1798), both adapted from the German of Kotzebue. During this interval, he was deeply engaged in politics. S.'s wit and sprightliness coruscated in society as brightly as they did in his comedies; he was an admirable table-companion—over a bottle, the best of then living good-fellows. With Fox and his wild set, these gifts made him a prime favourite; and through the influence of Fox it was that in 1780 he was returned to parliament for the borough of Stafford. In his politics, he faithfully followed Fox, and the Whig party from time to time had good service from their brilliant recruit. He never failed to amuse the House, and when stirred by the trumpet-call of a great occasion, he was capable of rising to heights of noble eloquence. In particular, his famous speech, urging the impeachment of Warren Hastings (q. v.), is still traditionally remembered as perhaps the very grandest triumph of oratory in a time prolific of such triumphs.

In 1792, S. lost his wife; and three years after, he was married again to a Miss Ogle, who brought him five thousand pounds, to S. no doubt welcome, though trifling as a relief to the difficulties in which he had become involved, and which more and more continued to accumulate upon him. Always the most reckless and improvident of mortals, he did not improve with time. His later years were years of wretched struggle, of which debt, duns, and dissipation may furnish a convenient alliterative summary. His health failed him with his fortunes; and his friends, not finding him in his sickness and adversity quite so amusing as formerly, naturally failed him also—notably and shamefully, the Prince Regent, whose dull brains over the wine-cup he had many a time been made use of to brighten. Some honourable exceptions there were, among whom the poets Rogers and Moore may be mentioned as steadily kind to him to the last. He died in London on the 7th July 1816, in his sixty-fifth year.

For the detail of his life, the biography by his friend Moore may be consulted; and a just and delicate appreciation of his genius will be found in Hazlitt's *Lectures on the Comic Writers*.

SHERI'F (Arab. noble), designates, among Moslems, a descendant of Mohammed, through his daughter Fatima and Ali. The title is inherited both from the paternal and maternal side; and thus the number of members of this aristocracy is very large among the Moslems. The men have the privilege of wearing green turbans, the women green veils, and they mostly avail themselves of this outward badge of nobility—the prophet's colour—while that of the other Moslems' turbans is white. Many of these sherifs founded dynasties in Africa; and the line which, now-a-days, rules in Fez and Morocco, still boasts of that proud designation.

SHE'RIFF (A.-S. *scir-gerēfa*, the reeve or fiscal-officer of a shire; compare Ger. *graf*), in English Law, is an officer whose duties are chiefly ministerial (for he has only a few trifling judicial duties). The office is of great antiquity. The sheriff was formerly chosen by the inhabitants, though probably requiring confirmation by the crown. But popular elections for that purpose were put an end to by a statute of 9 Ed. II.

which enacted that in future the sheriffs should be assigned by the chancellor, treasurer, and judges. Ever since that statute, the custom has been, and now is, for all the judges of the common law courts, with the Lord Chancellor, and Chancellor of the Exchequer, to meet in the Court of Exchequer at Westminster on the morrow of All Souls, and then and there propose three persons for each county to the crown. This is called the pricking of the sheriffs, and the crown afterwards selects one of the three nominated, and appoints him to the office. A sheriff continues in office for one year only, and cannot be compelled to serve a second time. The office is not only gratuitous, but compulsory, for if the person appointed refuses, he is liable to indictment. In practice, country gentlemen of wealth are appointed. In the city of London, the sheriffs are appointed not by the crown, but by the citizens. The sheriff has important official duties in elections of members of parliament. He is, by his office, the first man in the county, and superior to any nobleman while he holds office. He has the duty of summoning the *posse comitatus*—i. e., all the people of the county—to assist him in the keeping of the Queen's peace; and if any person above the age of fifteen, and under the degree of a peer, refuse to attend the sheriff after due warning, he incurs a fine or imprisonment. The chief legal duty which the sheriff discharges is that of executing, i. e., carrying out all the judgments and orders of the courts of law. It is he who seizes the goods of debtors or their persons, and puts them in prison. For this purpose, he has a number of persons called bound-bailiffs (or, in popular dialect, bumbailiffs), who in practice do this invidious work, and give a bond to the sheriff to protect him against any mistake or irregularity on their part. The necessity of this bond is obvious, for the doctrine of law is, that the sheriff is personally responsible for every mistake or excess made or committed by the bailiffs in executing the writs or process of the court, and frequent actions are brought against him by indignant prisoners, or debtors whose persons or goods have been arrested; and the courts watch jealously the least infringement of personal rights caused by these bailiffs. Every sheriff has also an under-sheriff and deputy-sheriff, the latter being generally an attorney, who takes charge of the legal business. One of the ornamental duties of the high-sheriff is to receive and escort the judges when holding the assizes in the provinces.

SHERIFF, in Scotland, is a title given to three county officials. The lord lieutenant is 'sheriff-principal,' and as such, though he performs no duties, takes precedence of all others in the county. The 'sheriff-depute' discharged all the duties of the office until quite recently, when the greater part of them has been practically devolved on the 'sheriff-substitute.' In Scotland, the office of sheriff is still that of a local judge, and not merely ministerial, as in England. The institution of the office is very ancient, and the jurisdiction, both civil and criminal, was, and still is, very extensive. By the statute 20 George II. c. 43, the office was put on a better footing. The principal, or high sheriff, was debarred from performing any judicial duty, and it was enacted that none should be appointed to be a sheriff-depute but an advocate of at least three years' standing. The sheriff-depute is disqualified from acting as advocate in any cause originating in his county, though in other respects he is at full liberty to practise. He holds his office for life or good behaviour, and he may be removed for misconduct on a complaint presented to the Court of Session by the Lord Advocate, or four freeholders of the county. The same statute gave each sheriff-depute power to appoint a sheriff-substitute, who must be an advocate, or a solicitor, of three years' standing. The sheriff-substitute was at first appointed during the pleasure of the sheriff-depute, but he now holds office *ad vitam aut culpam*, and being bound to reside within his county or district, and prohibited from taking other employment, while the sheriff-depute is now bound to attend the sittings of the Court of Session in Edinburgh, he, in practice, exercises the original jurisdiction attaching to the office. The civil jurisdiction of the sheriff extends to all personal actions on contract or obligations without limit, actions for rent, forthcomings, poindings of the ground, and possessory actions; and in these cases there is an appeal from the decision of the sheriff-substitute to that of the sheriff-depute. He has also a summary jurisdiction in small-debt cases where the amount in question is not above £12; and these cases are determined without the usual pleadings. The sheriff does not try civil causes with a jury. In criminal cases, the sheriff has jurisdiction in all the minor offences which do not infer death or banishment. He has also jurisdiction in cases of bankruptcy and insolvency to any amount. In small-debt actions, criminal and bankruptcy matters, there is no appeal from the sheriff-substitute to the sheriff-depute. The sheriff is responsible for maintaining the public peace, and when he is present his jurisdiction excludes that of the justices of the peace in riots and breaches of the peace. He has charge also of taking the precognitions in criminal cases. He revises the lists of electors, and returns the writs for the election of members of parliament; and this last is almost the only duty which he performs in common with the English sheriff. An idea of the multifarious duties performed by the Scotch sheriff, may be gathered from the statement that he exercises, within a comparatively small district, the functions which in England are exercised by the commissioners in bankruptcy, county-court judges, the stipendiary magistrates, recorders, revising barristers, and coroners. He has also duties as Commissary (q. v.).

The office of sheriff is one of the few which may be traced back to the Saxon times, and it appears originally to have been the same both in England and Scotland. The sheriff was at first elected by the freeholders to be the chief man of the shire, and seems to have possessed unlimited jurisdiction to keep the peace; to have presided in all the courts; to have punished all crimes, and have redressed all civil wrongs. This extensive jurisdiction has been gradually infringed upon, partly by the exercise of the royal prerogative, and partly by parliament. But in England it suffered more from the appointment to the office of men unfit to exercise judicial powers, and from the consequent usurpation of their functions by the supreme courts. The same causes operated in Scotland, though to a less extent. In England they resulted in the almost entire abolition of the judicial functions of the sheriff. In Scotland, they resulted in his being deprived of the more important parts of the criminal jurisdiction, particularly of the power to punish by death; and in his civil jurisdiction being limited mainly to questions affecting movables. In both countries, feudal principles prevailed so much over the old Saxon, that the office frequently came to be hereditary, which tended to a separation of the duties of the office into the honorary and the laborious—the former being performed by the principal sheriff, and the latter by the deputy. In Scotland, this separation was completed by the act of Geo. II., which entirely separated the offices, by the transference of the power of appointing the

depute from the principal sheriff to the crown. In England, this complete separation has never become necessary, from the fact of the sheriff's power having been much more crippled than in Scotland. Indeed, in England, so purely honorary and ministerial has the office become, that it has been held by a female, and in Westmoreland, the office was hereditary down to 1849. The duty of enforcing the orders of the supreme courts, which now in England are a principal part of the duties of the sheriff, appears to have been engrafted on the office —probably on the theory that these orders were those of the king himself. In Scotland, the sheriff has never been called on to enforce any writs except those actually and not merely in name proceeding at the instance of the crown.

SHERIFF-CLERK, in Scotland, is the registrar of the sheriff's court, and as such has charge of the records of the court. He registers, and, when required by the proper party, issues the sheriff's judgments. He also conducts what correspondence may be required. He has important duties to perform in regulating the summary execution which is issued in Scotland against the debtors in bills of exchange, promissory notes, and bonds, without the necessity of any judicial suit.

SHERIFF-MUIR, a name given to several moors in Scotland on account of the 'wapinschaws' which used to be there held, under the superintendence of the sheriff. The only moor of this name which appears prominently in Scottish history is situated in Perthshire, on the northern slope of the Ochils, two miles north-east of Dunblane, and was the site of the great battle between the adherents of the Houses of Stewart and Hanover, 13th November 1715. The former, who consisted of the northern clans under the Earl of Seaforth, and the western clans under General Gordon, numbering about 9000 in all, were on their march southwards, under the leadership of the Earl of Mar, to join the Jacobites who had risen in the north-west of England, when they were met by the Duke of Argyle at the head of 3500 disciplined troops. After lying under arms all night, the Macdonalds, who formed the centre and right of the Highland army, attacked the left of their opponents, and routed it so completely that the fugitives fled with all speed to Stirling, carrying the news that Argyle had been totally defeated. Argyle, however, with his dragoons had meantime driven the left of the Highlanders back for two miles, when the right and centre returned from the pursuit, and took him in rear; he then skilfully withdrew his men to a place of shelter, and remained facing his opponents till the evening, when he retired to Dunblane, and next day to Stirling. About 500 were slain on each side. As a mere battle, the victory lay with the Highlanders; but it was so little decisive, that it paralysed the action of the Jacobites almost as effectually as a defeat would have done.

SHERLOCK, Thomas, D.D., an English prelate, was the son of Dr William Sherlock, Dean of St Paul's, and was born in London in 1678. He was educated at Eton and Catharine Hall, Cambridge, where he took the degree of M. A. in 1701. In 1704, he obtained the Mastership of the Temple; in 1714, he became vice-chancellor of his college, taking the degree of D.D. in the same year; and in 1716, Dean of Chichester. Eleven years later, he was raised to the see of Bangor, was transferred to that of Salisbury in 1734, and in 1748 to that of London. He died in 1761. S. was a strenuous Tory, and supported the Church-and-State politics of his day with a sort of dull dignity. He displayed a good deal of diplomatic skill in his different official positions, whence Bentley nicknamed him 'Cardinal Alberoni;' his eloquence and learning were likewise of a very superior order, as may still be ascertained from his 4 vols. of *Sermons* (1755—1776), which were highly praised in their day. Besides these sermons, he wrote a variety of controversial treatises and pamphlets, all of which are now wholly forgotten.

SHERMAN, William Tecumseh, an American general, was born in Lancaster, Ohio, February 8, 1820. He entered the military academy of West Point in 1836, graduated sixth in his class June 30, 1840, and was appointed 2d lieutenant in the Third U. S. Artillery. During the winter of 1840—41 he served in Florida, was promoted to 1st lieutenant in November, 1841, and was afterwards stationed at Fort Moultrie, South Carolina. In 1846 he was sent with his company to California, where he remained during the Mexican war. In 1851 he received a commission as captain by brevet, to date from May 30, 1848, 'for meritorious services in California during the war in Mexico.' September 6, 1853, Captain S. resigned his commission, and accepted the position of manager of a banking-house in San Francisco. Early in 1860 he was appointed superintendent of the Louisiana State Military Academy; but, in a communication to the governor, dated January 18, 1861, he says, 'I beg you to take immediate steps to relieve me as superintendent the moment the State determines to secede; for on no earthly account will I do any act, or think any thought, hostile to or in defiance of the old government of the United States.' On the breaking out of the rebellion, S. offered his services to the government, and, May 13, 1861, was appointed colonel in the regular army, and commanded a brigade at the first battle of Bull Run. August 3, 1861, he was raised to the rank of brigadier-general. He greatly distinguished himself at the battle of Shiloh, and was soon afterwards commissioned major-general of volunteers. He assisted at the siege of Vicksburg, subsequently, and in the autumn of 1864 and spring of 1865, by a sweeping march through Georgia and the Carolinas, virtually closed the war, by compelling the surrender of General Joseph E. Johnston's army in North Carolina, April 26, 1865. In 1866 he was appointed lieutenant-general, and in 1869 became commander-in-chief.

SHERRY. See Wine.

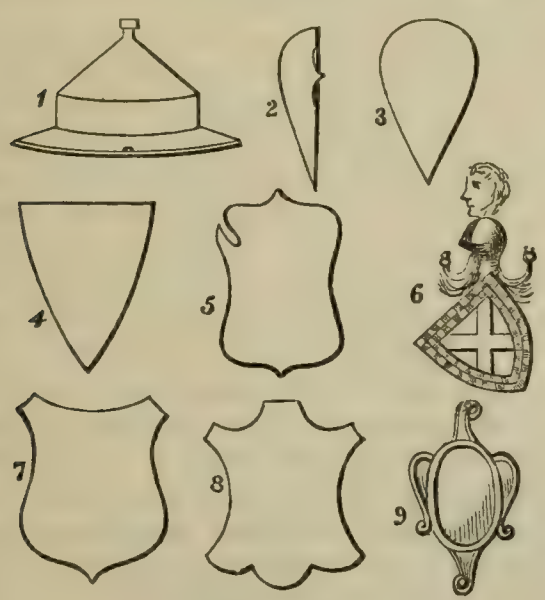
SHE'RWOOD FOREST, a stretch of hilly country in the west of Nottinghamshire, lying between Nottingham and Worksop, and extending about 25 miles from north to south, and 6 to 8 miles from east to west. It was formerly a royal forest, and the traditional scene of many of the exploits of the famous Robin Hood and his followers; but it is now almost wholly disafforested, and is occupied by gentlemen's seats and fine parks. The town of Mansfield and a number of villages are situated within the ancient bounds. Numerous remains of the old forest are still to be seen. The soil, which is principally a species of quartzose gravel, is in some places fertile, in others almost barren, and on the whole but of moderate quality.

SHE'TLAND, ZETLAND, or anciently HIALTLAND, is a group of about 100 islands, 23 of which are inhabited. The extreme north point—Hermaness in Unst—is in lat. 60° 50′ N., and long. 0° 53′ W. The southmost point of the group is on the Mainland, and is in lat. 59° 51 N., and long. 1° 15′ W. Fair Isle, however, is still further south, lying about midway between Orkney and S., to the last of which it belongs. The population of S. in 1861 was 31,670, females exceeding males by 5564. There

were in S. at the same date 6327 families, 1555 children at school, and no less than 5517 inhabited houses. In 1801, the pop. was 22,379, shewing an increase of 9209 during the last half century. Illegitimate births are rare. Lerwick may be said to be the only town in S.—Scalloway being the place next it in size and importance. As the centre of trade for S., Lerwick is in all respects well situated. It is the seat of the custom-house, courts of law, and other public offices, and has about 70 shops. It has a fine natural harbour, where the weekly steamer from Granton lies at anchor for a couple of days. Passengers, the mails, and a large portion of the exports and imports, arrive and leave by this steamer. The pop. of Lerwick is 3580, having more than doubled itself during the last 50 years. Fort Charlotte, now used as a prison, court-house, &c., is situated at the north end of the town—to the pretty and picturesque appearance of which it greatly contributes. Lerwick has no hotel, and only two licensed public-houses; there are, however, several lodging-houses. The chief articles of import are oatmeal, flour, tea, tobacco, spirits, sugar, cotton and woollen manufactured goods, timber, tar, salt, &c. The value of the meal and flour imported varies with the state of the S. harvest, but is believed to range from £15,000 to £20,000 annually—the grain raised in the country being always far short of the requirements of the population. Tea is largely consumed by all classes. No wood grows in the country, and the supplies of timber are drawn chiefly from Norway. This is almost the only foreign product which comes direct. Other articles liable to duty pass through the custom-houses at Leith and Aberdeen. In 1863, the number of vessels with cargoes arriving from ports in Great Britain was 149, having a register tonnage of 21,500, and from foreign ports 8, with a tonnage of 600. The principal articles of export are dried salt-fish, herrings, fish-oil, cattle, horses, eggs, and woollen articles knitted by hand. The last are remarkable for their beauty and fineness of workmanship. The steamer has taken away as many as 54,000 eggs at one time, and in 1862 it carried away 2093 cattle and 589 horses. About 3000 tons of dried salted fish are sent away annually, about one-half of them to Spain. The export of herrings varies from 4000 to 10,000 barrels. Chromate of iron is found in Unst, and has long been and still is an important article of exportation. Iron pyrites was at one time exported from Fitful, when the price of sulphur was high; and copper ores have been quarried and sent south from Sandlodge. The total exports exceed in value £100,000 annually.

Fishing is the chief employment of the male population, but each fisherman has usually a small farm, paying a yearly rent of £4 to £5—the labour on which is mostly performed by the female portion of his family. Spade-cultivation is almost universal among the small tenants, but the one-stilted plough may still be seen at work. Nearly every house has a quern or hand-mill, and every township has one or more of the old Norse water-mills. The spinning-wheel is common, but in some parts has not quite supplanted the spindle. Carts are very rare, and in many districts unknown. The sheep and ponies, which run at large on the Scaltald or Common, are marked, and the mark of each tenant is registered. Men and women still wear the *rivlin*, a kind of sandal, made of untanned leather. In some places, the land is still held runrig, and the tenants of a few islands on the west still hold their stock as steel-bow. Till a very late period, the Norse poor-law was in full operation—the poor being quartered on certain districts, going from house to house, and staying a longer or shorter period in each, according to the size of the occupant's farm. Many peculiar words, of Norse origin, are still found in the dialect of the Shetlander, whose English is soft and pleasant. Many of the people still eat their fish wind-dried and slightly tainted. The young men who do not devote themselves to the fishing at home, go to Davis' Strait and Greenland in whalers from Peterhead and Hull, or are employed as sailors from some of the large shipping-ports of the kingdom. They are much liked as seamen, being naturally intelligent, sober, and sedate. S. is joined with Orkney as a county, and has a constituency of about 180. The superficial extent of land is estimated at 400,000 acres, of which about 26,000 are under cultivation. The valued rent in 1864 was £28,799.

Ronas Hill, in the parish of North Mavine, is about 1500 feet above sea-level, and is the highest hill in the group. The cliff-scenery is in many parts exceedingly beautiful; that about Papa Stour not being surpassed anywhere in Scotland. The climate is moist and variable. The prevailing winds are south-east and south-west. The mean summer temperature is 49°·6, and the mean winter, 40°·2. The winters, therefore, are warmer than those of the south of Scotland, and the summers colder. The mean rainfall is 43·4 inches. The prevailing diseases are dyspepsia, rheumatism, and catarrh. The infant mortality is not high. Idiocy and imbecility are of frequent occurrence. Of the original inhabitants of S. we have little or no knowledge; but the physiognomy, aspect, character, and language of the present population point to a Norse or Scandinavian origin. (See ORKNEY.) Fair hair and blue eyes are exceedingly common.



Cairns, covering both the long and short stone coffins, with skeletons, clay urns, and weapons, and vessels of stone in them, have been found in Unst and elsewhere. Tumuli, consisting of burned stones and earth, are frequent, and in turning them over, the remains of rude buildings are found, and stone implements of various forms. Burghs or 'broughs'—circular strongholds of unhewn stone—are extremely numerous—generally on a cliff or headland, but not rarely on artificial islands in fresh-water lochs. The most perfect 'brough' in existence anywhere is in the island of Mousa. Underground houses have been found in Sandsting of a very rude type, and associated with them, there occurs the rudest form of stone implement which has hitherto been discovered. A stone of the Christian period, with an Ogham inscription, was found in Bressay. No Runic inscriptions are known to exist in the islands; monoliths are somewhat frequent. Stone circles are rare, and in no case of great size.

SHI'BBOLETH (Heb. ear of corn, or stream), the test-word used by the Gileadites, under Jephthah, after their victory over the Ephraimites, recorded in Judges xii. 6. It appears that the latter could not pronounce the *sh*, and, by saying *s*ibboleth, betrayed themselves, and were slaughtered mercilessly. It may be noticed that all those Hebrew names in the Old Testament, which commence with the *sh*, have now, through the inability of the Septuagint to render this sound in Greek, become familiar to us through the versions that flowed from it, as beginning with the simple *s*, e. g., Sem, Simon, Samaria, Solomon, Saul, &c. The word Shibboleth is used in modern languages in the sense indicated: viz., a test of speech and manners of a certain rank or class of society.

SHIEL, LOCH, in the west of Scotland, forms part of the boundary between the counties of Argyle and Inverness, separating the district of Moidart on

the north from those of Sunart and Ardgower on the south. The head of the loch is about 16 miles west of Fort-William. It is 15 miles long, and about one mile broad, and communicates with the sea by Shiel Water and Loch Moidart.

SHIELD, a piece of defensive armour, borne on the left arm, to ward off the strokes of the sword and of missiles. It has been constantly used from ancient times through the middle ages, till the invention of firearms rendered it useless. The large shield worn by the Greeks and Romans (Gr. *aspis*, Lat. *clipeus*) was circular, and often ornamented with devices. Another form of shield (Lat. *scutum*) was used by the Roman heavy-armed infantry, square, but bent to encircle the body. The early shield or knightly escutcheon of the middle ages was circular in outline, and convex, with a boss in the centre; the body generally of wood, and the rim of metal (No. 1). In the 11th c., a form came into use which has been compared to a boy's kite (No. 2), and is said, with some probability, to have been brought by the Normans from Sicily. It was on the shields of this shape that armorial designs were first represented. These shields were in reality curved like the Roman *scutum;* but after heraldry began to be systematised, we generally find them represented on seals, monuments, &c., as flattened, in order to let the whole armorial design be seen. In the 13th c., this long and tapering form began to give place to a pear-shape (No. 3), and a triangular or heater shape (No. 4). During the 14th c., these new forms became more generally prevalent, and the heater-shape, which was perhaps most frequently represented on armorial seals, began to approach more to an inverted equilateral arch. The same variety of forms, with some modifications, continued during the 15th c., a tendency appearing in all representations of the heater-shaped shield to give it more breadth below. A notch was often taken out in the dexter chief for the reception of the lance, in which case the shield was said to be *à bouche* (No. 5). Subsequent to the middle of

Shields.

the 14th c., when the shield came to be depicted as surmounted by the helmet and crest, the shield is often represented *couché*, that is, pendent from the corner (No. 6), an arrangement said to have originated in the practice of competitors hanging up their shields prior to a tournament, where, according to De la Colombière, if they were to fight on horseback, they suspended it by the sinister chief, and if on foot, by the dexter chief. A square shield denoted a knight-banneret. Shields of arms were often represented as suspended from the *guige*, or shield-belt, which was worn by the knights to sustain the shield, and secure it to their persons.

After the introduction of firearms made shields no longer a part of the warrior's actual equipment, the form of the shields on which armorial bearings were depicted, on seals, monuments, brasses, &c., varied greatly in form, and generally speaking, became gradually more tasteless, fanciful, and unmeaning (Nos. 7, 8, 9). A tendency has, however, been shewn in recent heraldry to recur to the artistic forms prevalent in the 14th and 15th centuries.

In early times, shields of the form which generally prevailed at the period, were exhibited on the seals and monuments of ladies; but about the 15th c., the practice began, which afterwards became usual, of unmarried ladies and widows (the sovereign excepted) bearing their arms on a lozenge instead of a shield.

The heraldic insignia of towns, corporations, &c., as well as individuals, are placed on shields. The bearing of Merchants' Marks (q. v.) in a shield was prohibited by the heralds of the 16th c. under severe penalties, and yet not a few instances are to be found on monumental brasses of these devices being placed on shields.

SHIELDS, North, a rising seaport of Northumberland, on the right bank of the Tyne, and at the mouth of that river, opposite South Shields, and eight miles east-north-east of Newcastle. It stretches more than a mile along the river-bank, and is rapidly extending westward. Possessing all the usual institutions, as churches, schools, theatre, custom-house, Sailors' Home, &c., it is not distinguished by any striking architectural features; and it is indebted to its rising trade and manufactures for its importance. There are numerous collieries in the vicinity, and the Northumberland Docks, which are within the borough, export more than a million tons a year. The resident shipowners of North and South Shields possess together upwards of 200,000 tons of shipping. The harbour is bordered with quays, and is spacious enough to accommodate 2000 vessels of 500 tons each. The building of wood and iron vessels, the manufacture of anchors, chain-cables, ropes, blocks, masts, and other articles of ship-furniture, are the principal branches of industry. North S. is included in the municipal and parliamentary borough of Tynemouth, the pop. of which (1861) is 32,321.

SHIELDS, South, a custom-house port, municipal and parliamentary borough, and market-town of Durham, on the south bank of the Tyne, and at the mouth of that river, 9 miles east-north-east of Newcastle by river and railway. The town stretches for two miles along the side of Shields' harbour, which is lined with numerous dockyards and manufactories. The Tyne Dock, containing 50 acres of water space, in which upwards of a million tons of coals are annually shipped, and a large import trade is carried on, is within the borough. The market-place is a spacious square in the centre of the town, near which is the large church of St Hilda. The town, with North Shields, is the principal port in the kingdom for the building of tug-steamers. There are large alkali and glass-works, and every kind of manufacture connected with shipping. A steam-ferry for passengers and carriages plies day and night between the two towns. Extensive piers, extending to a depth of 30 feet at low-water into the sea, have been constructed. Shields' bar has recently been removed by dredging, in order, with the piers, to form a harbour of refuge.

The sea-coast, in the neighbourhood, is interesting from the rocks and caves. The life-boat is a South S. invention. South S. sends one member to parliament. Pop. of borough (1861), 35,239.

SHI'ITES ('secretaries,' from the Arab. *Shiah*, *Shiat*, a party, a faction), the name given to a Mohammedan sect by the 'Sunnites' (q. v.), or orthodox Moslems. The S. call themselves 'followers of Ali,' and have special observances, ceremonies and rites, as well as particular dogmas of their own. The principal difference between the two consists in the belief of the S. that the Imamat, or supreme rule, both spiritual and secular, over all Mohammedans, was originally vested in Ali Ibn Abi Taleb, and has been inherited by his descendants, to whom it legitimately now belongs. The Persians are S.; the Turks, on the other hand, are Sunnites; and this division between the two nations dates chiefly from the califate of Mothi Lilla, the Abasside, in 363 H., when political dissensions, which ended in the destruction of Bagdad and the loss of the califate of the Moslems, assumed the character of a religious war. The S. themselves never assume that (derogatory) name, but call themselves *Al-Adeliat*, 'Sect of the Just Ones.' They are subdivided again into five sects, to one of which, that of Haidar, the Persians belong: the present dynasty of Persia deriving its descent from Haidar, a descendant of Ali. Ali himself is, by some of them, endowed with more than human attributes.—The S. believe in metempsychosis and the descent of God upon His creatures, inasmuch as He, omnipresent, sometimes appears in some individual person, such as their Imams. Their five subdivisions they liken unto five trees, with seventy branches; for their minor divisions of opinions, on matters of comparatively unimportant points of dogma, are endless. Yet, in this they all agree, that they consider the califs Abu Bekr, Omar, and Othman, who are regarded with the highest reverence by the orthodox Sunnites, as unrighteous pretenders, and usurpers of the sovereign power, which properly ought to have gone to Ali direct from the Prophet. For the same reason, they abominate the memory of the Ommayad califs, who executed Husain, a son of Ali, and they still mourn his death at its anniversary. They likewise reject the Abasside califs, notwithstanding their descent from Mohammed, because they did not belong to Ali's line.

SHIKARPU'R, the most important trading-town, and probably the most populous town, in Sinde, stands about 20 miles west of the Indus, half way between Multan and Kûrrachi. The district in which it stands is so low and level, that, by means of canals, which are supplied from the Indus, it is flooded every season. Its climate, notwithstanding, is said to be not unhealthy. The inundated quarters are extremely fertile and produce great crops. Groves, orchards, and fruit-gardens surround the town; sugar-cane is largely grown. S. is situated on one of the great routes by the Bolan Pass from Sinde to Afghanistan, and the transit-trade to that country and to Khorassan is important. The bankers and financiers of S. are known and trusted from Astrakhan to Calcutta. S. is the chief town of the state of the same name, which has an area of 13,679 sq. m., and 693,259 inhabitants. Pop. of the town estimated at 30,000, 20,000 of whom are Hindus, and the rest Mohammedans.

SHI'LKA. See AMOOR.

SHILLING, the name of a money in use throughout many European states, partly as a coin, and partly as a money of account. In all probability, the name, as well as the thing itself, is derived from the Roman *solidus*, which, with other remains of Roman institutions, was adopted by the Franks and other Germanic nations. See PENNY, SOLIDUS. Others give more fanciful derivations, as from *schellen*, to ring, on account of the particularly clear ring of the coin, and from St Kilian, whose effigy was stamped on the shillings of Würzburg. The *solidus shilling* of the middle ages has suffered various degrees of diminution in the different countries. Thus, the English silver shilling is $\frac{1}{20}$th of a pound sterling; the Danish copper one is $\frac{1}{96}$th of a ryks-daler, and $= \frac{1}{4}d.$ sterling; and the Swedish shilling is $\frac{1}{48}$th of a ryks-daler, $= \frac{1}{2}d.$ sterling. In Mecklenburg, Slesvig-Holstein, Hamburg, and Lübeck, the shilling is used as a fractional money of account (the $\frac{1}{10}$th of a mark, $\frac{1}{48}$th of a thaler), and as small silver change (each coin being a shade less in value than $1d.$ sterling). The French *sou* is another representative of the solidus. See POUND, MINT.

SHIN, LOCH, in the south of Sutherlandshire, is 18 miles long, and about one mile broad. The Shin Water, a famous trout-stream, carries the waters of the loch into Oikell Water. Loch S. abounds in common trout and salmon.

SHINGLES, flat pieces of wood used in roofing like slates or tiles. Such roofs are much used in newly-settled countries where timber is plentiful. The wood is chosen from among the kinds which split readily and straightly, and is usually some kind of fir. It is cut into blocks, the longitudinal faces of which are of the size intended for the shingles, which are then regularly split off in thicknesses of about half an inch.

SHIP (Ger. *Schiff* = *skif*; from the root *skap-* or *skaph-*, to scoop, dig; Gr. *skaphe*, a trough, a boat) is a term applied with great vagueness to all large vessels; while under *shipping* would be included vessels of all sizes, excepting boats without decks. Among seamen, the expression is said to be limited to vessels carrying three masts, with a royal-mast surmounting each; but the development of steam-navigation, in which the largest vessels have sometimes only a schooner rig, must have gone far towards obliterating this distinction.

SHIP-BUILDING. See NAVIGATION; NAVIES, ANCIENT AND MODERN; and NAVY, BRITISH. From crossing a river or lake on a floating log, or on two or more logs fastened together raft-wise, the first steps towards ship-building were probably Canoes (q. v.), and Coracles (q. v.). The earliest Egyptian drawings shew boats constructed of sawn planks, and having sails as well as numerous oars. So far as can be learned from ancient sculptures, the galleys of the Mediterranean at the dawn of civilisation appear to have been open, at least in the middle portion; to have been built with keel, ribs, and planking, and to have been strengthened cross-wise by the numerous benches on which the rowers sat. Ships continued, however, to be generally of small draught, for they were beached every winter; and Cæsar mentions, as a noteworthy circumstance, that some of the long ships with which he invaded Britain could only approach the shore to such a point that the soldiers in disembarking were breast-high in the water. The Romans built their vessels of pine, cedar, and other light woods; but their ships of war were of oak at the bows, clamped strongly with iron or brass, for use as rams—a custom now curiously revived after 2000 years of disuse. According to Cæsar, the Veneti first built entirely of oak. The speedy oxidation of iron bolts and fastenings led to their supersession by copper and brass about the time of Nero. Before this time, the planks had been calked with flax, and the seams had been pitched. There is evidence to shew that in Trajan's reign

sheathing of lead fastened on with copper nails had been used as a protection for the timbers from the devastating insects of the Mediterranean. With the decline of Roman greatness came a new era for ship-building. The hardy Norsemen had chopping seas and Atlantic swells to fight with; their ships differed much from the stately galleys and quinqueremes of the empire. Far smaller, they were built more stoutly, with bluff bows, and a lug-sail which could be braced well up to the wind. The Norse ships must have been of considerable power, for there is good evidence that they had visited the coasts of the New World at an early period. We have, however, very little knowledge of the construction of these vessels, except that they had high prows and sterns to resist the waves, and that they were calculated for sailing in opposition to the galleys, which were for rowing. The introduction of galleys by Alfred, pulled by 40 and 60 oars, and twice as long, deep, nimble, and steady as the Danish ships, kept the latter in check; but it also checked the development of ocean-navigation, for the galleys were only fit for shore-service. The ships gradually increased in size. Hardicanute had a galley pulled by 80 oars; and contemporaneously, the Venetians are said to have built ships of 1200 to 2000 tons. William invaded England in miserably small sailing vessels; but large—indeed very large—vessels appear to have existed in the time of Richard I. John systematised ship-building by establishing a royal dockyard at Portsmouth. Large ships constructed for sailing only seem to have come into general use, together with the mariner's compass, in the beginning of the 14th century. One hundred and fifty years later, the addition of the bowsprit added much to the sailing-powers of vessels.

In Ellis's Collection of Letters there is one, dated 1419, from John Alcêtre to King Henry V., concerning a ship building at Bayonne for that monarch. This letter is curious, as shewing how many of the present terms then existed, and also that the 'Kynges schyppes' were of considerable dimensions (e. g., 'the stemme is in hithe 96 fete; and the post 48 fete; and the kele ys yn leynthe 112 fete.') Before this period, ships had been built strong enough to encounter ice in the whale-fishery. From this period the history of ship-building is resolved into the history of individual parts, for the main principles of wooden ships were already established. In Henry VII.'s reign, the cumbrous fourth mast began to be dispensed with; in that of his successors, shifting top-masts came into fashion, the lofty stems and sterns (which must have precluded sailing on a wind) fell gradually into disuse. Port-holes were invented at least as early as 1500. In 1567, there were cutter-rigged vessels in the British seas. In the century ensuing, naval architecture was much improved by Mr Phineas Pett, his son Peter, and by Sir Anthony Deane; but the best naval architects were not in England. Within the present century, the introduction of steam has led to the building of ships with finer lines, both for bow and stern. About 1836, iron was introduced as a material for ship-building, and is now employed almost equally with wood.

Adverting now to the actual art and practice of ship-building, the subject is divisible into two distinct portions—the theoretical, known as *Naval Architecture;* and the practical, called *Ship-building.* The naval architect designs the form of a ship with reference to the objects intended in her construction, to the speed required, powers of stowage, &c.; while the ship-builder works from his drawings, and gives practical effect to the theoretical design.

Naval architecture on a theoretic basis is of recent date, for, as in all cases, practical efforts, more or less in the dark, have preceded by many ages the theorems of the man of science; nor is it at present by any means an exact science. Results continually occur which take by surprise the best masters; and great as have been the strides both in theory and practice, many of the most successful ships have been but happy experiments. The laws of flotation and resistance are, of course, the foundation of the science, and for these we must refer to the articles on HYDROSTATICS and HYDRODYNAMICS; but very trifling changes in the shape of the body immersed, the position of its centre of gravity, &c., produce apparently disproportionate results on the sailing-powers of a ship. In regard to speed, the resistance is, theoretically, as the square of the velocity; but, practically, it increases in a greater ratio, since the water piles in a wave before the bows, and leaves a temporary hollow before it closes in at the stern. To avoid this wave at the bow, and give good steerage-power to the rudder, finely-pointed extremities are desirable; but if these points be too fine, they will cease to be self-sustaining in the water, and will detract from the general buoyancy of the ship, while they will tend to raise the centre of gravity above the metacentre. Apart from these considerations, the finer the build, the less are the stowage-power and steadiness. It will thus be seen how many points a naval architect has to take into account in designing the lines of a ship. It would be beyond the scope of an elementary article like the present to give the complicated rules by which the areas of sections, solid contents, and centres of gravity of ships are calculated; but it is necessary to say that they have to be computed with the utmost nicety. Theory has as yet failed to point out clearly what should be the proportions between the length, breadth, and depth of a ship; but the following principles may be stated as the results of experience:

An increase of length gives an increase of displacement of water, and therefore of carrying-power; if this be not desired, it allows of finer lines forward and aft, and consequently greater speed. It also increases the resistance to lee-way. The greater friction of the water on the longer sides does not appear to be material. Against the increase is to be set a diminished power of turning, tacking, and wearing. It also involves a more careful balancing of weights in the fore and after portions of the ship, for the momentum of a small weight may become large in a long vessel, from being such weight multiplied into the square of its distance from the ship's centre of gravity.

The increase of breadth gives greater stability to the ship, and, by allowing of more sail, indirectly greater speed; but directly, it increases the resistance to the water. Of course, greater breadth enables greater bulk to be carried. Depth is a question dependent on the seas to be navigated, the object for which the ship is intended, and many other reasons. It is to be borne always in mind that the consumption of stores on a long voyage will change the draught of a ship considerably. Practice has proved unequivocally that ships sail better for drawing more water aft than forward.

Passing now to the actual designing of vessels: the architect works on paper only; he has therefore to shew on a flat surface, for the builder's guidance, the exact position, curvature, and relief of every line and point in his proposed structure. He accordingly draws three plans, on each of which every point of the ship is traceable: the *sheer-plan,* shewing all lines of length and height;

the *half-breadth plan*, lines of length and breadth; and the *body-plan*, which shews breadth and height. From these combinations, the exact position of every point is determinable. Figures 1 to 3 shew those plans, called *construction drawings*, on the same scale for the *Great Eastern* steamship. The

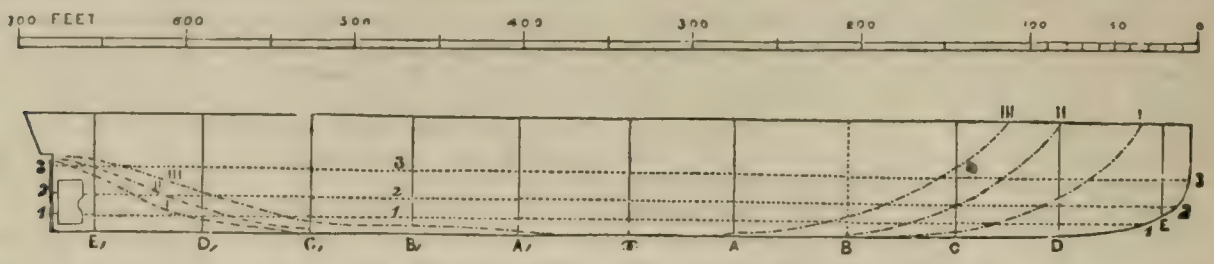


Fig. 1.—*Great Eastern*—Sheer Plan.

sheer-plan represents, in its outside line, a vertical plane through the keel. The dotted lines, 1, 2, 3, are the edges of supposed horizontal planes drawn at various heights. The curved lines, I, II, III, are the edges, as they would appear on the outer covering of the ship, of vertical planes drawn parallel to the central plane through the keel. The uprights, A, B, &c., $A_,$, $B_,$, &c., are the edges of supposed planes drawn at given distances from the line of greatest breadth X, at right angles to the plane

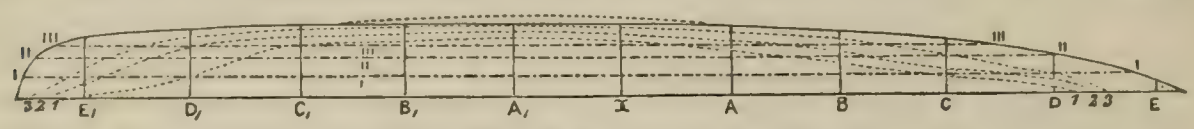

Fig. 2.—*Great Eastern*—Half-breadth Plan.

through the keel. The half-breadth plan represents one half of the ship's upper deck, as regards the black outer line; the horizontal, vertical, and cross sections of the sheer-plan appearing again under different conditions. The vertical longitudinal sections become straight lines parallel to the keel; the horizontal sections appear as curves taken at different heights on the vessel's sides. The body-plan is the ship looked at end-on; the outer line being her cross section at the line of greatest breadth, and the horizontal and vertical sectional lines appearing at right angles to each other. The lines on the left side correspond to the cross sections of the after-body (that is, the portion of the ship nearer the stern than the line of greatest width), and shew the curvature of the ship's sides towards the stern; while in a similar manner those on the right side shew the curvature up to the bow. Of course, in working-drawings from which ships are to be actually built, the scale employed would be very large; and instead of three or four sectional lines in each direction, a great number would be inserted for the guidance of the builder. With these three plans in hand, the workman has the exact position of every point in the ship's exterior coating exactly defined. Even the unprofessional observer need not strain his imagination greatly to clothe these flat plans with their dimensions of length, breadth, and depth, and to conjure up before his eyes the precise form of the goodly ship represented.

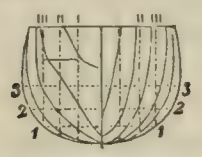

Fig. 3.—*Great Eastern*—Body Plan.

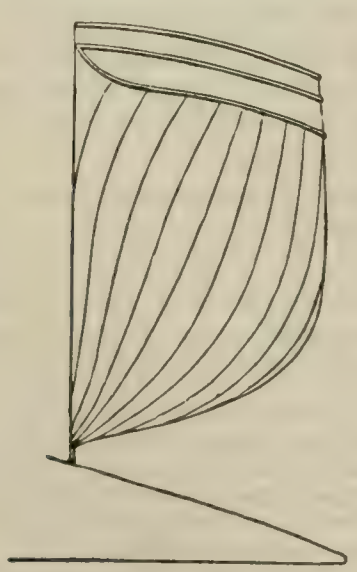

Fig. 4.—Clipper—*Lord of the Isles.*

Before leaving these plans, it is right to state that the *Great Eastern* is somewhat peculiar in her lines; few body-plans are so flat in the bottom; and on the other hand, she is unusually convex at the bow. In proof of this, fore-bodies of two celebrated vessels, and the half-breadth of their bows, are shewn in figs. 4, 5.

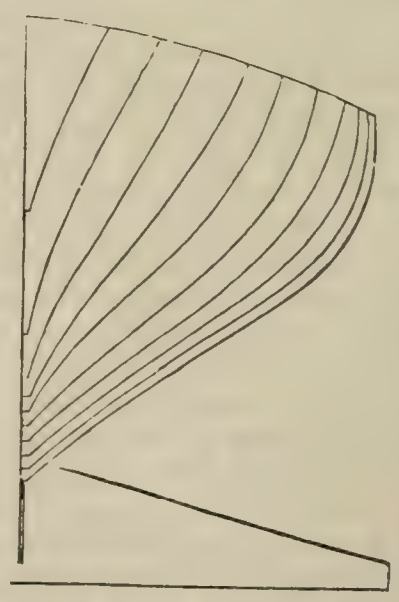

Fig. 5.—Yacht—*America.*

With the completion of the construction drawings the work of the naval architect ceases, except as regards any necessary subsequent supervision.

It is then to be decided of what material the ship shall be constructed. Of the many woods employed—oak, teak, and fir, are those most commonly used; or iron may be resorted to; or, again, the ship may be of wood and iron combined. The building of a wooden and of an iron ship are quite distinct operations, the requisite strength being obtained in a different manner in each case. It is necessary, therefore, to consider separately the principles of wooden ship-building and iron ship-building; and as the most time-honoured, and as yet the most general process, we will first deal with the art of the shipwright who forms the vessel of timber.

Wooden Ship-building.—The first process is to develop, or 'lay off,' on the *mould-loft floor*, certain full-size working sections of the required ship. These are taken from the construction drawings, and are built up of planks. The combinations of these pieces of plank shew the shape in which the several timbers will have to be cut, to impart the necessary curvature and strength.

The next step in actual construction is to prepare the slipway, by raising a number of strong blocks of timber a short distance apart, on which the keel shall rest, and which shall sustain the entire ship when built. These blocks are composed of several pieces, and it is of the utmost importance that their upper surfaces be in an exact line. That line is made at an inclination of $\frac{5}{8}$ths of an inch to a foot; and the keel of the ship, and the ship itself, have consequently that slope to the horizon while building. This inclination is for the facility it affords in launching the completed vessel. On the blocks is laid the keel, which may be called the back bone, and is certainly by far the most important timber in the ship. From it start the ribs, the stem, and the sternpost; so that any serious accident happening to the keel, involves the breaking up of the whole structure. It is therefore made of great strength, being, in a first-rate, no less than 20 inches square. The material is usually elm, on account of its toughness, its non-liability to split, and the fact that immersion in sea-water preserves it. The pieces of which it is composed are united by the strongest kind of scarph joint (see CARPENTRY).

To afford a firm footing for the planking of the ship, a rabbet, or angular groove, is cut in the side of the keel, as in fig. 6. Here the side *a* represents the rabbet, as usually cut in the merchant service; *b*, as made in the royal navy. The advantage of the latter system is, that thicker planking can be worked in, affording better lateral support to the keel, and that there is less disruptive leverage when the ship takes the ground. The *false keel* is placed below the true keel, after all the bolting through the latter has been accomplished. It consists of elm, 4 to 6 inches thick; and is but lightly secured, in order that if the ship runs ashore, the false keel may readily come off, and let the vessel go free. It is so put on that its joints come midway between the scarphs of the keel. To fix it, it is necessary to knock away, one by one, the blocks on which the keel rests, which is done at the time the weight of the ship is transferred from the blocks to the cradle resting on the bilge-ways. See LAUNCH.

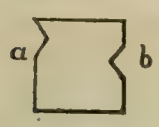

Fig. 6.—Rabbets of the Keel.

What the keel is to the bottom, the stem and sternpost are to the bow and stern of the ship, forming the keys from which the ends of the planking (technically called the 'butts') and all longitudinal supports start. Each is, of necessity, of great strength, and rises from the respective extremities of the keel. The *stem* is fastened to the keel by scarphs, called the *boxing*, and within it is the *apron*, and perhaps a false-post also, to impart additional strength, as shewn in fig. 7. The *stern-post* has to bear the rudder, and is usually made, when possible, of one piece of timber; it is united to the keel by a mortise and tenon joint. In large vessels, an inner post is sometimes worked on to the sternpost for extra security. In screw-steamers, there is a second sternpost, forming the forward support for the screw.

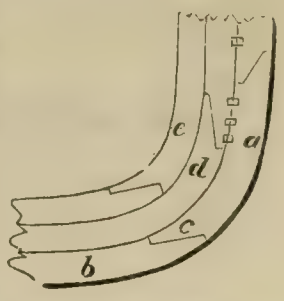

Fig. 7.—Stem.
a, stem; *b*, keel; *c*, boxing; *d*, apron; *e*, stantion.

The extreme outlines of the ship being now established, the builder proceeds with the timbers to form the bottom and sides, which together constitute the *frame*, corresponding to the ribs in an animal. The ribs form the sides of the ship, and are placed at from 2 feet 6 inches to 3 feet 9 inches from centre to centre. Above the water-line, the spaces between them are filled in solid with timbers of equal thickness. For this purpose, in the midship-body the keel is crossed at right angles, or nearly so, by certain timbers which form the *floor*. One mode of arranging the component pieces is shewn in fig. 8. The

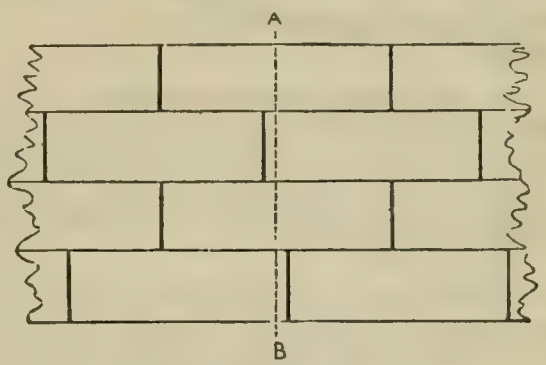

Fig. 8.—The Floor.
A, B, Middle Line of Keel.

keel is let about three-fourths of an inch into a groove running along the bottom of the floor, while above the floor, the *keelson* is a massive timber, parallel to the keel. The keel and keelson are bolted firmly together by long copper bolts, which pass through the timbers of the floor, and completely fix the latter. Beyond the floor-pieces, and forming the curvature of the sides, are the *futtocks*. The heels of these timbers rest on the butts of the floor-timbers. There may be a greater or less number of futtocks, according to the size of the ship. On the heads of the uppermost futtocks, rest the heels of the *top-timbers*, which, with any *lengthening pieces* which may be necessary to give height, form the complete ribs. The floor, futtocks, top-timbers, and lengthening timbers are united to each other by dowels and bolts. As an additional strengthening to the frame in large vessels, *side* or *sister keelsons* are bolted on to the floor or futtocks, a short distance on each side of the principal keelson. Fig. 9 shews a section of a complete rib, with the several parts. Having now formed the ribs for the midship-body, in which they are placed at right angles to the keel, it is necessary to consider their form in the fore and after cant-bodies. Here the right angle can be no longer maintained between the timbers and the keel, since they have to be

gradually rounded through a quadrant of a circle until the foremost timbers, on each side of the stem, face to the front. This arrangement involves

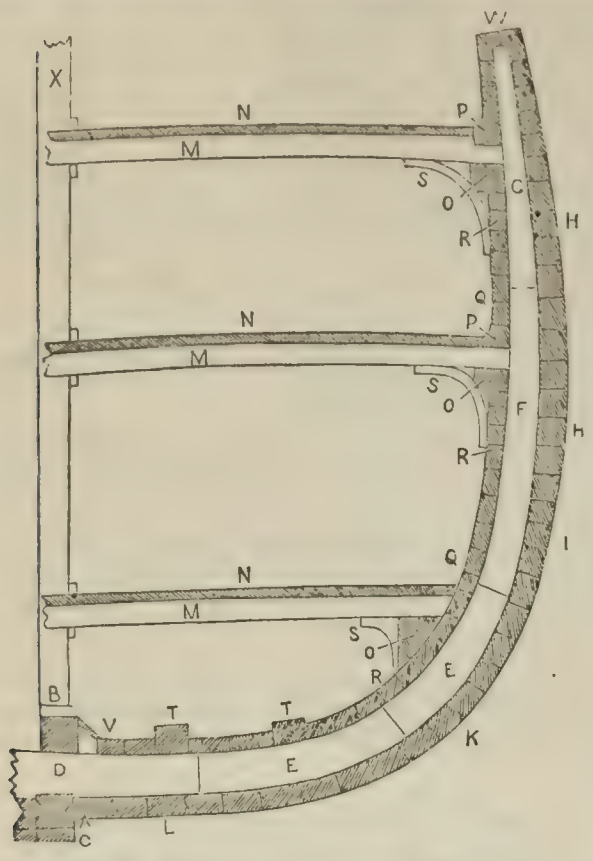

Fig. 9.—Rib and Decks in section.

A, keel; B, keelson; C, false keel; D, floor; EE, futtocks; F, t p-timber; G, lengthening piece; HH, wales; I, diminishing planks; K, bottom planks; L, garboard strakes; M, beam; N, deck; O, shelf; P, waterway; Q, spirketting; R, clamps; S, knees; T, side-keelsons; V, limber strakes; W, rough-tree rail; X, mast.

the ribs being set at a diminishing angle to the keel, as seen in fig. 10. The foremost cant-timbers are the *knightheads*, forming, with the stem, a bed for the bowsprit; next to these are the hawse-timbers, through which the hawse-holes are pierced. In order that the cant-timbers may sit firmly on the keel, they are made narrower at the bottom than at the top. But the canting forward or aft is not the only peculiarity of the cant-bodies; for at its extremities the ship becomes sharp downwards as well as endways. It consequently ceases to be practicable to have floors of any flatness across the keel. The half-floors and

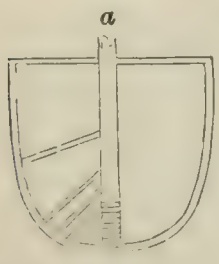

Fig. 10.—Cant-body, seen from above.
a, keel.

Fig. 11.

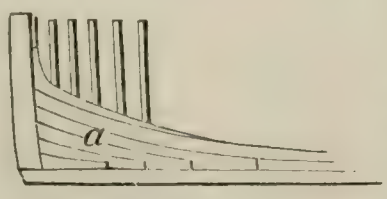

Fig. 12.—Deadwood (*a*).

first futtocks are made in one piece, slanting more directly upwards; they pass rapidly from their flat position, through that shewn in fig. 11, to the state called *deadwood*, shewn in fig. 12. The deadwood consists of timbers worked above the keel, and of the same width with it, and is practically a heightening of the keel. The deadwood imparts a wedge-like shape to the vessel. In screw-steamers, the after-deadwood is almost wholly cut away to form the aperture for the screw.

Having built the main skeleton, as it were, of our ship, the skin is the only thing remaining to complete its exterior. This is represented by thick wooden planking, fastened on to the ribs, the lowest layer pressing into the rabbet of the keel, and the highest reaching to the uppermost bulwark. The thickest planking is at the bends or wales, marked H in fig. 9, where it varies from 4½ inch in small vessels to 10 inch in ships of the first class. Very thick plank is technically termed *thickstuff*. Below the wales, the planks are reduced gradually in thickness: those first occurring are called the 'diminishing plank,' still of oak: under this, on the rounding, fir is used under the name of 'bottom plank,' except the last five or six planks from the keel, which are of elm, and are called 'garboard strakes.' Every complete line of planking from stem to stern is styled a *strake*. As the trees from which thick planks are cut are parts of cones—i. e., with the plank much wider at base than at top—the planks are worked alternately as in fig. 13, which is called 'top-and-butt.' Other forms

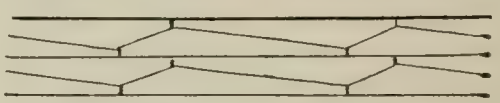

Fig. 13.—Planking; top-and-butt.

of working are 'fair-edge' and 'anchor-stock,' which do not call for particular description, but are less economical than top-and-butt. The planks are fastened to the ribs by bolts; one through each rib constituting 'single fastening;' two, 'double fastening;' and one and two alternately, 'single and double fastening.' 'Dump fastening' consists in using alternately one bolt and one dump or bolt-nail, which is hammered to a head without and within. Wooden treenails are, however, frequently employed, as less in weight than copper, and less liable to split the wood. The comparative utility of wood and copper fastenings for the strakes, is still a disputed point.

In a well-constructed ship, the filling in of the timbers to a level above the water-line should be so accurately formed that she would float without her planking; but when the latter has been well caulked, it is certain that it adds greatly to the dryness of the ship, while it aids materially in binding her several parts together.

At frequent intervals across the ship, and at the heights of the several decks, are inserted the *beams*, which are solid masses of timber, either in one piece or scarphed. These prevent the ship from collapsing, and at the same time support the decks. The beams and decks are shewn at M and N respectively in fig. 9. To support the beams on each level, a strong timber or *shelf* is worked round the interior of the ribs. Above the ends of the beams, similar timbers or *waterways*, though somewhat smaller, are worked round the inner frame. The inside is planked above the water-line similarly to the outside. The planks above the waterways as high as the ports or windows are *spirketting* (Q), those below the shelf and above the ports are the *clamps* (R). The decks and beams curve upwards at the middle, forming a very depressed arch, partly for drainage, and, in men-of-war, partly to counteract the recoil of the guns. When weight is piled on

the deck, the tendency is consequently to force the ship's sides outwards. This it is endeavoured to overcome by using large knees or iron brackets, which maintain a direct connection between the beams and ribs (see S in fig. 9). At the bow and stern, additional rigidity is given by the ribs being connected by *breast-hooks* and *crutches*. When the beams are well established, the hatchways and mast-holes are traced out with their *coamings* resting on *carlings*, which are cross-pieces between the beams, and their *head-ledges* resting on the beams themselves. This done, the deck is laid down of straight-grained hard wood; the planks are calked and pitched between, until the deck or platform becomes perfectly water-tight.

Along the inside of the bottom are laid the *sister keelsons*, or *side keelsons*, if the ship be large, and all spaces are filled up with planking, except the width of one plank next the keelson on each side, which is left for a drain to carry all refuse-water to the foot of the pumps. A plank called the 'limber' is placed across this gutter, to keep solid rubbish out. The inside planking next the limbers goes by the name of the *limber-strakes*.

We have now completed the principal parts of the hull of a wooden ship. There are, of course, numerous matters of detail, as bitts, channels, capstans, &c., all of which are provided for while the ship is building, but into the details of which we cannot enter.

Iron Ship-building.—Iron affords in many respects a better material for ships than wood. In the first place, the same strength may be obtained with less weight; secondly, iron plates can be rolled to any curve, so that the combinations necessary for strength in wooden vessels can be avoided. Ships are built of boiler-plate riveted closely together. The denominations of the several parts in a wooden ship are adhered to. There is the keel, formed by some makers boxwise, but more commonly

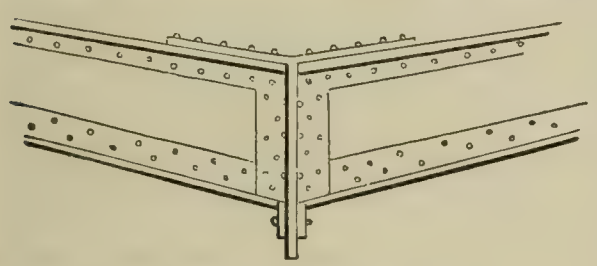

Fig. 14.—Keel of an Iron Ship.

in the simpler shape shewn in fig. 14; from it rise the ribs, which are really girders, formed of plates, following the curve of the side. Keelson and side keelsons rise within, but rather for sustaining the cargo off the ship's bottom than for the strengthening purposes to which they are applied in wooden vessels. Outside the ribs the strakes are riveted on in large plates, varying in thickness according to the strength required from about $\frac{1}{16}$ths to about $\frac{5}{16}$ths of an inch. In some ships, similar plates are laid over the inside of the ribs, thus forming two water-tight skins for the vessel's flotation, the space between being divided into compartments by the ribs themselves. Firmly riveted to the ribs, which they brace together while they prevent compression, are the iron beams, usually flat-headed T-shaped, as in fig. 15. Resting on these, and fastened to them, is a thin plate or deck of iron, and over that wooden planking to form the actual deck. The waterways are of iron. In most large iron ships, there are water-tight bulk-heads extending completely across the vessel, and dividing her into separate compartments, a few of which suffice to float the ship even if the others from any accident become filled with water. A framework is fastened to the sides and bottom, and a diaphragm of iron plate stretched within it to form the bulk-head. Except in shape, an iron ship differs little from a tubular bridge, and as she can be strengthened to any degree by uprights and cross-trees, it follows that the parts of an iron ship can be made to afford far more mutual support, and therefore more strength, than those of a wooden one. Comparative durability is a separate question; but the preference is believed to rest with iron, if proper precaution be taken to prevent rust.

Fig. 15.—Section of T-shaped Beam.

Ships of Iron and Wood conjointly.—The French, far more than ourselves, have introduced iron into timber-ships, particularly for the beams, where the gain, for strength, lightness, and cross-tying, is unquestionable. They use iron plates, also, instead of inner planking with advantage, as saving space and weight.

In war-ships, the combination of iron and wood is mainly limited to iron-plated ships. These are either built with a wooden frame, outside which massive plates of iron are riveted, or with a powerfully cross-braced iron frame, on which a coating of perhaps 20 inches of timber is worked as a backing for the defensive iron armour. These vessels have of late occupied much attention, several specimens of each sort having been tried. The armament may consist of a broadside battery, or of heavy guns in revolving cupolas. See TURRET SHIPS.

Internal Arrangements of a Ship.—Whether the vessel be of iron or wood, her internal design must follow the purposes for which she may be required. As a general principle, the ship is divided into a greater or less number of platforms, floors, or Decks (q. v.), devoted to various purposes. In a ship-of-war, a large portion is required for the men, the remainder being occupied by warlike stores, provisions, and coal. In a merchant-vessel, far less space is allotted to the crew, and far more to the cargo. In every ship, a space must be provided for the carriage of provisions and water proportionate to the number of the crew and the intended duration of voyages. A steamer differs from a sailing-vessel in requiring a large compartment amidships to be kept clear, without being crossed by decks, for her engines and boilers. As at this part the vessel loses the lateral hold of beams, and the longitudinal ties of decks, the sides have to be otherwise strengthened. In screw-steamers, to the height of the boss of the screw above the keelson, a tunnel, known as the *screw-alley*, has to be kept open for the shaft of the screw from the engine-room to the stern. This tunnel necessarily narrows as it enters the dead-wood, until it affords little more room than the actual shaft demands. The heavier portion of a cargo, as coal and water, is carried immediately above the keel, so that the centre of gravity may be as low as possible, and for the same reason the engines and boilers are placed as low down as practicable. For various details concerning the formation and arrangement of ships, the reader is referred to detached articles descriptive of the respective portions, as DECKS, MASTS, CAPSTAN, CHAINS, CHANNELS, HOLD, KEEL, &c.

SHIP-MONEY, a tax had recourse to in England at various times, but especially in the reign of Charles I., for the equipment of a fleet. In 1007, when the country was threatened by the Danes, a

law was made obliging all proprietors of 310 hides of land to equip a vessel for the protection of the coast. Elizabeth, at the time of the threatened Spanish invasion, required the various ports to fit out a certain number of ships at their own charge; and so great anxiety was shewn by the public for the national defence, that London and some other ports furnished twice as many vessels as had been demanded. It was in 1626 that Charles first had recourse to an impost of this description, requiring each of the maritime towns, with the assistance of the neighbouring counties, to arm a given number of vessels, 20 being required from London. In 1634 the tax was extended over the whole kingdom. A general spirit of resistance was immediately aroused, not so much in consideration of the amount of the tax, as of the objectionable feature, that it was imposed by the arbitrary authority of the king alone, which had come to be regarded as an unwarrantable stretch of the royal prerogative. In 1637, the celebrated John Hampden, a gentleman of property in Buckinghamshire, resolved to confront the power of the government by disputing the legality of this exercise of the prerogative, and resolutely refused payment of the impost, an example in which he was followed by nearly the whole county to which he belonged. He was prosecuted in the Exchequer Chamber for non-payment, and his trial was watched with great interest and anxiety by the nation on account of the constitutional point involved in it. The judges, four excepted, pronounced in favour of the crown; but the trial had the effect of thoroughly arousing the public mind to the danger of the imposition of taxes by the royal authority alone. The Long Parliament, shortly after its meeting in 1640, voted ship-money illegal, and the sheriffs and others who had been employed in assessing it or collecting it to be delinquents; and cancelled the sentence against Hampden.

SHIPPING. See MARITIME LAW.

SHIP-WORM. See TEREDO.

SHIPWRECKS, in ancient times, were deemed the property of the crown, but by a statute of Henry I., the harsh consequences of this law were avoided whenever any person escaped alive out of the ship; and in Henry II.'s charter it was declared that if either man or beast escaped alive, the goods should remain to the owners if claimed within three months; and the courts of law still further refined away all these harsh rules. Many nice distinctions have been made as to what goods constitute wreck, which is distinct from goods floating. See FLOTSAM. By the recent Merchant Shipping Act, 1854, which extends to the United Kingdom, the Board of Trade has the superintendence of all matters relating to wreck, and to jetsam, flotsam, and ligan. Receivers of wreck are appointed for various districts, and have power to summon assistance. When wreck is found by any person, he must give notice to the receiver of wrecks, and if nobody claim the property within a year, it is sold, and the proceeds, after paying salvage and other such expenses, are paid into the Exchequer. Persons plundering wreck are guilty of felony, and may be punished with three to fourteen years' penal servitude; and any person exposing false signals to cause wreck, may be sentenced to penal servitude for life.

The following results are given in the Abstracts of Returns made to the Lords of Committee of Privy Council for Trade, for the year ending 31st December 1863. The number of wrecks and casualties near the coasts of the United Kingdom for 1863 was 1664. The annual average number for the nine years ending 31st December 1863 is 1339. It is, however, stated in the Report accompanying the abstracts that the last five years of the period ending with 1863 were exceptionally stormy, January, February, and November 1861 having added upwards of 460 to the casualties of that year; while the heavy westerly gales in the beginning and end of 1863 added 930. During the five years ending 1858, the total casualties are stated at 5594, giving a mean of 1118$\frac{4}{5}$; while for the five years ending 1863 they were 7441, giving a mean of 1488$\frac{1}{5}$. The maximum occurs in 1863; the minimum, 987, in 1854. Of the total in 1863, 331 arose from collision; 1333 from other causes; and of this 1333, the result was total loss in 503 cases. The following table may be interesting:

CASUALTIES FROM CAUSES OTHER THAN COLLISION.

Year.	Total Loss—from					Partial Damage—from					Total.
	Stress of Weather.	Carelessness.	Defect of Vessel.	Various Causes.	Cause Unknown.	Stress of Weather.	Carelessness.	Defect of Vessel.	Various Causes.	Cause Unknown.	
1859	298	84	42	70	33	308	97	42	88	5	1067
1860	278	103	49	40	6	367	110	49	72	7	1081
1861	302	89	48	49	25	424	102	56	75	1	1171
1862	242	72	25	96	20	386	115	42	144	8	1150
1863	332	61	31	65	14	550	115	30	126	9	1333
	1452	409	195	320	98	2035	539	219	505	30	5802

From Table No. 6 of the Abstracts of Returns quoted from, it appears that the greatest number of casualties, on an average of the five years ending with 1863, has taken place on the east coast of Great Britain—i. e., between Dungeness and Duncansby Head; and by Table 21, it is shewn that the casualties most fatal to life have occurred in the Irish Sea.

In 1863, 3906 British vessels suffered from casualties at sea, while the annual average for 10 years was 3343, and the actual number for 1869 was 2986, or nearly 10 for each working day. An analysis of wrecks and casualties reported in *Lloyd's List* during the year 1869 shews the total number of disasters to have been 10,972, of which there were cases of total loss 2006, constructive loss 156, great damage 1154. Of 3316 instances of loss and great damage reported in *Lloyd's List*, 2986 are posted in *Lloyd's Loss Book*.

SHIRA'Z, a celebrated city of Persia, and the capital of the province of Fars, in lat. 29° 41′ N., long. 52° 38′ E., was formerly a very flourishing city, and the ordinary residence of the Persian monarchs, but is now singularly divested of its ancient splendour. It is situated in a wide plain, on one of the limestone ledges which shoot out from the great West-Persian mountain system, 112 miles from the Persian Gulf, and 35 south-west of the ancient Persepolis (q. v.). It is enclosed by walls nearly four miles in circumference, and, previous to the great earthquakes which have repeatedly laid it in ruins, contained many splendid mosques, bazaars, caravanseras, and other public buildings. The houses, which are mostly built of stone, are superior in appearance to those of most other Persian towns; and the adjoining portion of the plain is of exuberant fertility, and is laid out in vineyards and in rose-gardens of great extent, which, at the season of bloom, emit a fragrance, which may be felt at a great distance. The principal manufactures are silk, cotton, and woollen goods, cutlery, firearms, glass, and earthenware, as well as wine (or rather liqueur) and oil of roses. The lapidaries are famous throughout Persia. The trade of the town is transacted in the *Bazar-i-Wukell*, which is about half a mile long by 40 feet wide and affords accommodation to

several hundred shopkeepers. S. carries on trade with Yezd, Ispahan, and Bushire, from the last of which towns it receives Indian and European goods. The city was founded in 697 A.D., and from its beautiful situation and charming climate, became a favourite resort of the Persian princes; but a destructive earthquake in 1812 laid a large portion of it in ruins, and another in 1824, which cost the lives of 4000 of the inhabitants, completed the wreck of its prosperity. It was, however, rebuilt, and had attained a pop. of 40,000 (its pop. previous to 1812 having been almost 60,000), when a third and more terrible visitation of this destructive agent in April 1853 laid almost the whole town again in ruins, and caused the death of 12,000 people. It has since been partially rebuilt in a somewhat inferior style, and its pop. is now estimated at 30,000. It is celebrated for the number and eminence of the scholars and poets to whom it has given birth; chief of these is Sibuyah, the first of Arab grammarians; Hafiz (q. v.), the 'Anacreon' of Persia, whose tomb is half a mile north-east of the Ispahan gate; and Saadi (q. v.), whose mausoleum is 22 miles to the north-east.

SHIRE (Sax. *sciran*, to divide), a term which seems to have originated in the 8th c., and is applied to the districts, otherwise called counties, into which Great Britain is divided. A considerable number of the counties of England, as Kent, Essex, Surrey, Norfolk, Suffolk, were formed out of the petty kingdoms of the Anglo-Saxons, which, with the advancing tide of centralisation, were gradually becoming consolidated into one great kingdom. As early as 800, an entry in the Saxon Chronicle relates that kings had ceased to reign among the *Hwiccas* (the inhabitants of the district afterwards known as Worcestershire), and that they were governed by an ealdorman acting under Cynwulf, king of Mercia. This substitution of ealdormen (or earls) for kings marks the gradual organisation of the counties. It was sometimes found convenient to split up a kingdom into several shires. The civil, military, and judicial head of the shire was the ealdorman, whose office was not necessarily hereditary, though it had sometimes a tendency to become so. Twice a year he held the shire-mote, in which he and the bishop presided with equal jurisdiction. Among other questions which would come before the shire-motes were those that related to the boundaries of the respective shires. As a border thane pushed his occupation towards the frontiers of the shire to which he belonged, and came into collision with the occupants of the neighbouring shire, questions necessarily arose which could only be settled by a compromise arranged by the two shire-motes, and these compromises may account for the irregular jagged boundaries which separate shire from shire, and occasional isolation of particular portions. Yorkshire, Durham, Cheshire, and Worcestershire derived their name from their ancient bishoprics. Various shires which had once an existence in the north, as Norhamshire, Islandshire, Hexhamshire, Hallamshire, Bamboroughshire, have merged into others. The term shire is nearly synonymous with county, yet not quite so, as there are certain counties with whose names the affix 'shire' is never used. One explanation which has been given of this usage is, that the object of the addition of the syllable 'shire' is to distinguish the county from the town of the same name, and that it is therefore only applicable to counties bearing the same name with their county town. Another explanation is, that shire being a word of Anglo-Saxon origin, is not properly applied to any of the English counties except those which formed part of the larger Anglo-Saxon kingdoms. Neither of these reasons is exactly correspondent with the actual usage, by which shire terminates the names of all the English counties except the following: Northumberland, Cumberland, Westmoreland, Durham, Norfolk, Suffolk, Essex, Sussex, Middlesex, Kent, Surrey, and Cornwall. In Cheshire, we drop the final syllable of the town of Chester. Berkshire, Shropshire, and Hampshire are never used in their simple form, though sometimes abbreviated into Berks, Salop, and Hants. Shire is applied to all the Welsh counties except Anglesea.

In Scotland, the English tendencies of the sovereigns from the time of Malcolm Canmore to the war of succession, and the tide of immigration from the south, brought in, among other innovations, the division into shires. Its introduction seems to have begun early in the 12th century. Twenty-five shires or counties are enumerated in a public ordinance of date 1305. Nearly all the counties of Scotland may receive the terminal addition of shire. It is not applied to the island county of Orkney, and seldom to the counties of Bute and Caithness. Kirkcudbright is neither a shire nor a county, but a Stewartry. See STEWARTRY. The Irish counties are not generally called shires.

In England, south of the Tees, there was a subdivision of the shires into *hundreds*, which originally, in theory at least, seem to have been districts inhabited by 100 or 120 families; and were in some localities called *wapentakes*, these hundreds or wapentakes being further subdivided into *tythings*, inhabited by ten free families; and it became incumbent on every one to be enrolled in a tything and hundred for the purposes of civil government. In some of the larger counties there was an intermediate division to which that into hundreds was subordinate. Yorkshire had and still has its *Ridings* (q. v.), Kent had its *Lathes*, and Sussex its *Rapes*. The division into hundreds and tythings never penetrated into the four northern counties of England, or into Scotland, where the *ward* and *quarter* were the immediate subdivisions of the county.

England possessed three *counties palatine*—Cheshire, Lancashire, and Durham—of which the earls formerly possessed all the judicial and fiscal powers of the crown, all now annexed to the crown (see PALATINE). Similar privileges belonged to the earldom of Stratherne in Scotland.

SHIRÉ, a river of South-eastern Africa, has its source in Lake Nyassa, from which it issues in lat. 14° 28′ S., and after a southerly course of 250 miles, joins the Zambesi. It flows through a cotton and sugar producing country of vast extent, is 80 to 150 yards broad, 12 feet deep, and never varies more than 2 or 3 feet from the wet to the dry season. Its current travels at the rate of 2½ knots an hour. The navigation is obstructed by cataracts over a space of 35 miles, in which it falls 1200 feet.

SHIRWA, or TAMANDUA, a lake of South-east Africa, north end 30 miles south-east of Lake Nyassa, lat. of centre 15° 10′ S., long. 35° 40′ E. It is of an oval shape, tapering to the south; length, 60; breadth, 10 to 23 miles; and 1800 feet above the sea-level. It is surrounded by elevated land. On the west, between the lake and the River Shiré, Mount Zomba rises to 7000 feet. Several small rivers enter the lake on the south and west.

SHI'SHAK (in hieroglyphs, Shashank, the Susak or Susakim of the Septuagint, and the Shishak of the Hebrew version, the Sesonchosis or Sesonchis of Manetho), the name of several monarchs of the 22d, or Bubastite Egyptian dynasty, supposed to have descended from foreign settlers in Bubastis, and to have been of Shemitic origin. The kings

of this name were S. I., the first monarch of the dynasty, whose name is found in the portico built by the Bubastite dynasty at the great temple of Karnak, and on several statues of the goddess Pasht, which probably came from Luxor. Jeroboam fled to S. from the pursuit of Solomon, who wished to kill him, and lived there during the lifetime of Solomon. On the death of this monarch, Jeroboam quitted Egypt, and contended with Rehoboam for the possession of the crown. This struggle caused the division of the kingdom of David into two states, that of Israel and Judah. In the fifth year of Rehoboam, S. marched to Jerusalem with an army of 12,000 chariots, 60,000 cavalry, and an innumerable number of infantry, composed of Troglodytes, Libyans, and Ethiopians. He took the city, the treasures of the temple, and all the gold bucklers which Solomon had made. The conquest of Jerusalem is found recorded on the monuments of Karnak, on which S. I. is represented dragging before the god Ammon three files of prisoners, inscribed with various names of places, amongst which are Judæa, Mageddo, Ajalon, Mahanaim, and other towns taken by S. in his line of march.

SHITTIM-WOOD. It is not certain what kind of wood is meant by this name in the Old Testament. The Ark of the Covenant was made of it, and probably it was a kind of wood distinguished both for beauty and durability. It has generally been supposed to be the wood of the *Acacia Nilotica*, which, however, is deficient in both these qualities. Another supposition is, that the wood of a species of olive is meant, *Olea similis*, which possesses them both, and is particularly remarkable for its durability.

SHIVES, a name used by cork-cutters to designate the small bungs used to close wide-mouthed bottles, in contradistinction to the phial-corks used for narrow-necked bottles.

SHO'A, a kingdom of Africa, the most southern division of Abyssinia, in lat. 8° 30′—10° or 11° N., long. 38°—40° 30′ E. Its boundaries, however, are by no means fixed, that on the W., where S. is bordered by the Galla tribes, being specially variable. An extensive tract in the east of the kingdom, between the capital, Ankobar, and the river Hawash is called Efat. The character of the country, and the condition of the people, are described under ABYSSINIA (q. v.).

SHOCK, COLLAPSE, AND REACTION. It is well known that some forms of injury, as, for example, a blow on the pit of the stomach, may occasion death without leaving any visible trace of their operation in the body; and, indeed, life may occasionally be destroyed even by sudden and powerful mental emotions. In such cases as these, death is said to result from shock, the actual cause of death being the sudden arrest of the heart's action, consequent on the violent disturbance given to the nervous system. Instead of actual death, the condition known as *collapse* is more frequently induced, in which the patient lies in a state of utter prostration, and apparently on the verge of dissolution. The face, and even the lips, are pale and bloodless; the skin is cold and clammy, and drops of sweat are often seen on the forehead. The features are contracted, and there is great languor in the general expression. There is extreme muscular debility, and the sphincter muscles sometimes relax, so that there is involuntary discharge of the contents of the bowels and the bladder. The pulse is quick, and so feeble as often to be almost imperceptible, and the respiratory movements are short and weak, or panting and gasping. The patient is in some cases bewildered and incoherent, in others drowsy, and sometimes almost insensible. Nausea and vomiting, with hiccup, are not unfrequent symptoms; and in the case of children, convulsions are often present.

When a person recovers from a state of collapse, he passes into a condition termed *reaction*, which often lasts for several hours. The first symptoms of this favourable change are improvements in the state of the pulse and the respiratory actions, recovery of the power of swallowing, an increased temperature, and an inclination to move from the supine position to one side. A slight degree of feverishness then often ensues, after which the skin becomes moist, the patient falls asleep, and awakes convalescent. As a general rule, the longer the symptoms of reaction are delayed, the greater is the danger, and if several hours pass without any sign of the commencement of reaction, there is little hope of recovery. If the reaction is imperfectly developed, a condition may supervene which is known as 'prostration with excitement,' which may terminate either fatally or favourably, and into the symptoms of which our limited space will not allow us to enter further than to remark that a peculiar delirium, closely resembling *delirium tremens*, is most commonly present.

The principal causes of collapse (as given by Mr Savory in his article 'Collapse, and the General Effects of Shock upon the System,' in Holmes's *System of Surgery*) are:

'Injuries sudden and severe, or extensive, as contused and lacerated wounds, involving a considerable amount of texture—the crushing of a limb, for instance. Burns present familiar and striking examples of extreme collapse, produced by this cause. Under this head, too, come capital operations. Injuries of very important organs, as the liver or other of the viscera, or of the joints, or other organs abundantly supplied with nerves. Pain alone, when intense and protracted, has proved fatal in this way; and it appears in a case related by Sir A. Cooper, that sudden relief from great agony was attended by the same untoward result. Certain poisons operate in this manner, depressing the system so suddenly and severely as to produce a state of collapse; tobacco, for example; and drastic purgatives have in some cases induced a similar condition.'

The effects of shock are aggravated by loss of blood; and hæmorrhage alone, if sudden and profuse, will produce collapse. General debility and old age favour the influence of the shock, and much depends upon the idiosyncrasy of the patient; an injury which will produce no apparent effect on one man, often producing a serious and persistent impression on another.

The following are the most important points in regard to treatment: The patient should be kept in a horizontal position, with the head on the same level as the body, and he should not be raised till decided symptoms of reaction appear. The best stimulus is brandy, given in the form of hot brandy and water. 'Its effects,' says Mr Savory, 'are most certain and decided, and it suits the stomach best. It will remain when all other stimulants are rejected. The state of the circulation and the temperature are the guide to its use. If no effects are apparent after an ounce or two have been swallowed, it is very questionable if any advantage will be gained from a larger quantity.' At the same time, heat should be applied to the pit of the stomach and the extremities, by means of hot flannel, hot-water tins, or, in their absence, bottles containing hot water, and other appliances. Nourishment, in the form of beef-tea, should closely follow the stimulants; the two may be combined

with the greatest advantage, and as the system rallies, the latter may be entirely replaced by the former.

In those cases in which a patient is in a state of extreme collapse from an injury requiring a capital operation, such as the amputation of a limb, the operation should be performed as soon as his condition will admit of it; and although it should not be undertaken while the prostration is extreme, it is not necessary, nor even advisable, in Mr Savory's opinion, to wait for complete reaction; and this is the opinion of most of our best surgeons. Moreover, in these cases, the use of chloroform is not expedient; for, in the first place, it cannot be safely administered to a patient so depressed; and, secondly, the chief reason for its employment is wanting, for a person in a state of collapse is comparatively insensible to pain. For further information on this subject, the reader is referred to Travers *On Constitutional Irritation*, and to the excellent article of Mr Savory, from which we have freely borrowed.

SHODDY formerly meant only the waste arising from the manufacture of wool; it now has a wider and much more important signification, and is almost wholly understood to mean the wool of woven fabrics reduced to the state in which it was before being spun and woven, and thus rendered available for remanufacture. Woollen rags, no matter how old and worn, are now a valuable commodity to the manufacturer; they are sorted into two special kinds, the rags of worsted goods and the rags of woollen goods, the former being made of *combing* or long-staple wools, and the latter of *carding* or short-staple wools. The former are those properly known as *shoddy*-rags, and the latter are called *mungo*. Both are treated in the same way; they are put into machine called a *willey*, in which a cylinder covered with sharp hooks is revolving, and the rags are so torn by the hooks, that in a short time all traces of spinning and weaving are removed, and the material is again reduced to wool capable of being reworked. It was formerly used as a means of adulteration and cheapening woollen cloths, but it is now found of greater advantage in making a class of light cloths adapted for mild climates and other purposes.

The name is a purely technical one, which has arisen amongst the Yorkshire spinners, and is derived from *shed*, the term having been formerly applied by the operatives to the *flue* or waste shed or thrown off in the process of spinning. See WOOLLEN MANUFACTURES.

SHOEING OF HORSES. In olden times, horses generally went unshod, as they now do in many eastern countries; but our Macadamised roads and paved streets, our fast paces and heavy loads, would speedily wear away the stoutest hoofs, and a rim of iron has accordingly been long in use as a protection. In style and pattern, the horse's shoe varies almost as much as his master's boot, and like it, when badly made, or unskilfully fitted, produces serious inconvenience, and even leads to accidents and diseases. When the feet are strong and properly managed, nothing is better than a plain shoe of tolerably uniform breadth and thickness, carefully fashioned to the shape of the foot. But many good authorities prefer what is called a seated shoe, which has a level part for the crust to rest upon, and within that the inner half of the shoe towards the sole surface is bevelled off. This seated shoe is thus wider than the plain shoe, and hence affords greater protection for a weak or flat sole. For faulty or diseased feet, special forms of shoes are suitable. In all healthy feet, the shoe should be fitted to the foot, and not, as is commonly done, the foot cut to fit the shoe. Another frequent error of keeping the shoe short and spare at the heels must be avoided. For roadsters, the toe of the fore-shoes should be slightly turned up, which greatly obviates tripping. The hind-shoes are generally thickened, and sometimes turned down at the heels. The number of nails required must vary somewhat with the weight of the shoe and soundness of the horn; five is the minimum, nine the maximum. It is important, however, that the shoes be firmly held on by as few nails as possible. In a saddle-horse with sound feet, three on the outside, and two on the inside, should suffice to hold a well-fitted shoe. Horses for heavy draught are generally shod in Scotland with tips and heels, which afford increased firmness of tread, and greater power, especially when dragging heavy loads. To preserve the foot in a sound state, the shoes should be removed every month. When the shoe is carefully taken off, the sole-surface on which it has rested should be rasped, to remove any ragged edges and any portions of adhering nails. Having for a month been protected from the wear to which the exposed portions of the foot are subjected, it will probably have grown considerably, and, in a stout hoof, will require to be cut down with the drawing-knife, especially towards the toe. Except in very strong feet, and in farm-horses working on soft land, the surface of the sole uncovered by the shoe seldom requires to be cut. It is the natural protection of the internal delicate parts, and must be preferable to the leather and pads often artificially substituted for it. The bars must likewise remain untouched, for they are of great service in supporting weight; whilst the tough, elastic frog must be scrupulously preserved from the destructive attacks of the knife, and allowed uninjured to fulfil its functions as an insensible pad, obviating concussion, and supporting weight. When the shoe is put on, and the nails well driven home, they should be broken off about an eighth or even sixteenth of an inch from the crust, and hammered well down into it. This obviously gives the shoe a much firmer hold than the usual practice of twisting off the projecting nail close to the crust, and afterwards rasping down any asperities that still remain. When the shoe is firmly clinched, the rasp may be very lightly run round the lower margin of the crust just where it meets the shoe, to smooth down any irregularities, but all further use of the rasp must be interdicted. The clinched nails, if touched, will only have their firm hold weakened; nor must the upper portions of the crust, which blacksmiths are so fond of turning out rasped and whitened, be thus senselessly deprived of those external unctuous structures, which render the unrasped foot so tough and sound, and so free from sandcracks. To prevent the hoof becoming too dry and hard, it is advisable, especially in roadsters, and in hot weather, to stop the feet several times a week with a mixture of equal weights of lard, tar, bees-wax, and honey, with about one-fourth part of glycerine, melted together, well stirred, and preserved in pots for use. Fuller details on this subject will be found in a little volume entitled *Notes on the Shoeing of Horses*, by Lieutenant-colonel Fitzwygram, 15th (the King's) Hussars; and in a paper on 'Horse-shoeing,' by Mr Miles, published in the *Journal of the Royal Agricultural Society of England*, and reprinted in a separate form by Mr Murray, Albemarle Street, London.

SHOES, SHOE-TRADE. Clothing for the feet, whether in the form of sandals or shoes, has been in use in every country aspiring to civilisation in

ancient and modern times. The rudimentary shoe is a sandal consisting of a sole, held to the foot by straps and thongs, as represented in fig. 1. Such were the common Egyptian and Greek shoes, to which the shoes of the peasantry of the Abruzzi, in

Fig. 1.

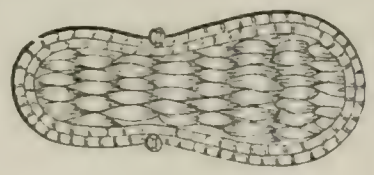

Fig. 2.

the south of Italy, bear a close resemblance. In Egypt, however, the ordinary materials for shoes were strips of the papyrus interwoven like a mat; an example of a sole of this kind is given in fig. 2. As is seen from paintings on the walls of Thebes, shoemaking formed a distinct trade in the reign of Thothmes III., 1495 B.C., or about the period of the flight of the Israelites. In the adjoining illustration, fig. 3, a sketch is presented from Thebes of two

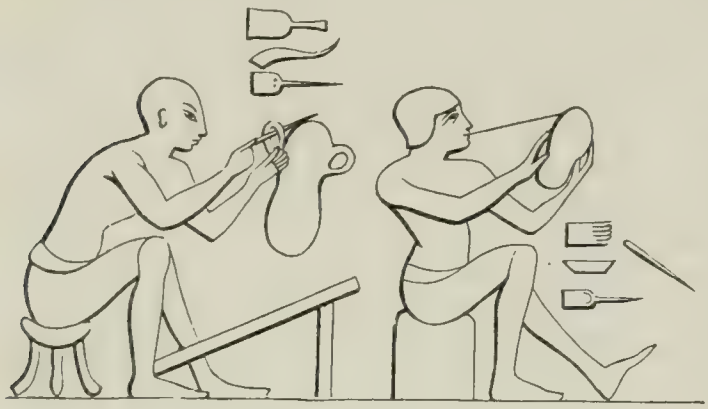

Fig. 3.

Egyptian shoemakers at work, with the tools of their profession beside them. The first workman is piercing with his awl the thong at the side of the sole, through which the latchets were passed; before him is a low sloping bench. The second workman is equally busy sewing a shoe, and tightening the thread with his teeth. It appears from one of the figures over the first workman that the bent awl of the modern shoemaker is of extreme antiquity. In one of the Greek dramas, allusion is made to the daily earnings of the shoemaker; and we know from historical record that the streets of Rome were encumbered with the stalls of shoemakers in the reign of Domitian. The shoe of the ancient Hebrews was a species of sandal. For ladies, the sandal, translated 'shoe' in the Scriptures, was highly ornamental: 'How beautiful are thy feet with shoes, O prince's daughter' (Cant. vii. 1). Ornamented slippers are still a luxury in the East. The foot-coverings of the Romans were various in character, from the simple sandal and slipper to the boot, which extended up the leg. When the shoe covered the whole foot, it was termed *calceus;* the calceus of a particular form and of great strength worn by the Roman soldier was known as *caliga*. From wearing these shoes, the common soldiers were designated *caligati*. The Emperor Caligula was so called from having worn *caliculæ*, or little boots, when he served as a youth in the ranks of the army. Usually, the caligæ of the soldiers were studded with hob-nails.

Reference is made in Scripture to different symbolical usages in connection with sandals or shoes. The delivery of a shoe was used as a testimony in transferring a possession: 'A man plucked off his shoe, and gave it to his neighbour: and this was a testimony in Israel' (Ruth iv. 7). In cases of this kind, the throwing of a shoe on a property was a symbol of a new proprietorship or occupancy: 'Over Edom will I cast my shoe' (Psalm lx. 8). From these ancient practices, in which the shoe was symbolical of contract, perhaps comes the curious old custom in the north of England and Scotland of throwing old shoes for good luck after a bride and bridegroom on departing for their new home. We learn from several passages in the New Testament that the untying of sandals, as involving considerable trouble, was assigned to servants; the unloosening of the thongs, translated 'latchets,' accordingly became a symbol of servitude: 'The latchet of whose shoes I am not worthy to unloose' (Luke iii. 16). The carrying of the shoes of another is spoken of as a similar mark of inferiority: 'Whose shoes I am not worthy to bear' (Matthew iii. 11).

St Crispin and his brother Crispinian have long been regarded as the patron saints of shoemakers. According to medieval legend, these personages were natives of Rome, and having become converts to Christianity, travelled into France and Britain to propagate the faith, everywhere supporting themselves by making shoes, which they sold to the poor at a very low price—one part of the legend being that an angel supplied them with leather. It is said that they suffered martyrdom in England towards the end of the 3d century. The memory of St Crispin, of whom we chiefly hear, has, from time immemorial, been kept up by processions and other festivities in his honour on October 25, which is known as 'St Crispin's Day.' Under this saintly tutelage, shoemaking has attained to the distinctive appellation of the 'gentle craft;' and above most other mechanical professions, is noted for the number of individuals who have risen from it to eminence. See an amusing but scarce work, *Crispin Anecdotes*. The sedentary and solitary nature of the craft, as hitherto conducted, has possibly had some influence in

Fig. 4.

producing a degree of thoughtfulness, while the act of hammering his leather is calculated, as some imagine, to stimulate the mental energy of the operative. If there be any real virtue in the sitting attitude of the shoemaker, a corresponding

evil attends that method of carrying on his operations. In every profession, sitting at work in a close atmosphere is particularly injurious to health. Statistics assure us that out of 10,000 artisans who sit at their labour, 2577 fall sick, and 95 die, annually; whilst as regards an equal number of those who alternately sit and stand, only 1713 sicken, and 61 die. To remedy this crying evil, a member of the profession, Mr J. Sparkes Hall, London, has invented a simple and inexpensive work-bench, at which shoes may be made standing. Of this standing-bench, we offer a sketch in fig. 4. A few days' practice, we are told, renders the workman as expert with the standing-bench as if he were seated according to the old plan, and he can execute closing with less fatigue and considerably more cleanliness. The only kinds of work in which sitting is more convenient are rounding the soles, lasting, and fitting, for which a seat may be employed.

The fashion of shoes, as has occurred with other articles of dress, has undergone innumerable changes. At one time, shoes were pointed to an extravagant degree; and in last century, the high heels of ladies' shoes became a monstrosity. Shortly after the beginning of the present century, the most marked improvement was the making of shoes right and left; the substitution of latchets for buckles about the same period was also a step in advance. In our own day, the general disuse of the shoe proper, and the introduction of short ankle-boots, are the chief changes of fashion. A proposal for a more perfect adaptation of shoes and boots to the shape of the foot, is noticed under Foot. The shoemaking trade, as at present conducted in Britain, is divided into two departments—the bespoke and the ready-made or sale business. The larger department hitherto has been that in which customers bespeak boots and shoes by having them made to measure; but it is generally giving way to the plan of buying articles ready-made. The cause of this is exceedingly obvious. The process of measuring is usually very imperfect, owing, among other reasons, to the want of lasts to suit every variety of feet, as well as the too general indifference to meet individual peculiarities. On this account, and even at the risk of purchasing an inferior class of goods, the public are becoming daily more disposed to encourage the ready-made trade. Accordingly, large quantities of boots and shoes in innumerable varieties are now made and supplied wholesale by manufacturers for the retail dealers. Northampton, Stafford, and Leicester are considerable seats of this manufacture in England; and from certain districts in France, there are increasing importations, chiefly of a cheap kind of ladies' shoes.

The plan of making boots and shoes by isolated workmen at their own homes, has been found quite incompatible with the modern necessities of trade. As in the case of the handloom weaver, the shoemaker of the old school has had to succumb to machinery. After an unsuccessful struggle to oppose the introduction of sewing-machines, these are now coming generally into use, and men are employed in large numbers together in what may be called shoe-factories. This manufacture has long been a staple trade of Massachusetts, in which state the quantity of boots and shoes fabricated annually is numbered by millions of pairs. Recently, a machine has been introduced into the American shoe-trade for fixing the soles to the uppers by means of pegs, the inventor being a person in Salem, Massachusetts. A pair of boots or shoes can be pegged in two minutes. These pegged goods are disposed of wholesale in boxes, and may be seen in retail stores all over the United States. As evidence of the important character of the shoe-trade in Massachusetts, it may be mentioned that a few years ago there were as many as fifteen members of the 'gentle craft' in the legislature of that state.

According to the State Census of Massachusetts in 1865, 55,160 persons were employed in that state in the manufacture of boots and shoes, valued at $52,915,243. In 1869, the annual value of boots and shoes produced in the United States was $246,250,000, into which leather and other materials entered to the amount of $130,169,608.

The product of Philadelphia for 1870 was valued at $7,724,809, and employed 6215 hands.

SHO'LA, the white pith of the leguminous plant *Æschynomene aspera*, a native of the East Indies. With this substance, which is exceedingly light, the natives of India make a great variety of useful articles, especially hats, which being very light and cool, are in great request. Helmets made of shola are much used by the British troops in India.

SHOOTING, with intent to wound, is felony in the law of England, and punishable with penal servitude for life. The offence consists in shooting at another, or drawing a trigger, or in any other manner attempting to discharge loaded arms. It is not, however, an offence unless there was a possibility of injuring some person; the intent must not only exist, but the relative situation of the parties must be such that serious injury might have ensued. The extent of the actual wound is immaterial.

SHORE. See Sea-shore.

SHORE, in Ship-building, is a strong prop or stanchion placed under the bottom or against the side of a ship, to keep her steady on the slip or in dock. Shores are also used to support or prop up a building during alterations.

SHOREDITCH. See Tower Hamlets.

SHO'REHAM, New, a seaport, and parliamentary borough of Sussex, on the left bank and at the mouth of the Adur, six miles west of Brighton. The town arose when the harbour of Old Shoreham, now a mile inland, became silted up. Pop. *of the parish* (1851) 2590; (1861) 3351. This increase is attributed to the extension of the ship-building trade here, and partly to the recent discovery of oyster-beds on the south-west coast of the Channel. More than 80 smacks, each manned by five hands, are employed in this parish in the oyster-trade. The parliamentary borough, which includes the *Rape* (see Sussex) of Bramber, contains 32,622 inhabitants.

SHORTHAND, a very useful art, by means of which writing is made almost as expeditious as speaking. In ordinary longhand, many separate motions of the pen are required to form each single letter: thus *m* requires *seven* motions, *k* requires *six*, *h five*, *t four*, *l three*, &c. But as syllables include vowels as well as consonants, and often two, or even three, and sometimes four consonants occur before or after a vowel, the number of motions requisite to write syllables in longhand is very great. The monosyllabic words *long* and *short*, for instance, require respectively *fourteen* and *seventeen* motions of the pen; while such syllables as *stream*, *splints*, *strength*, &c., require from *twenty-one* to *twenty-six* motions. Abbreviated writing is thus a necessity in all cases where language has to be written from ordinary delivery. Some stenographers make use of the common alphabet, and merely contract words by the omission of letters.

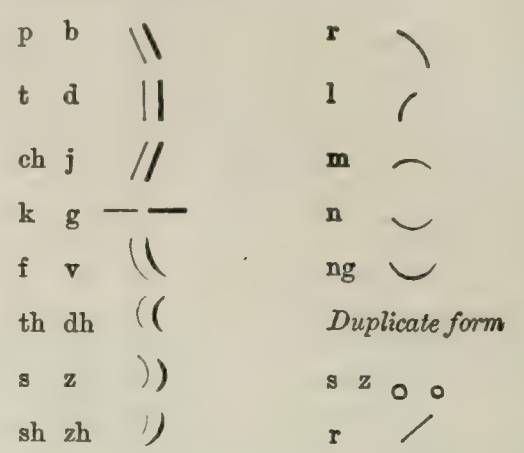
They would, for instance, write the last sentence thus:

So. ste g. ma. u. of th. com. alph. & me. contr. wo. by th. om. of let.

This is not properly *shorthand;* the latter term is limited to writing which is both abbreviated in spelling, and simplified in the forms of the alphabetic characters. Much attention has been paid to this art in Britain during the last 300 years, upwards of 200 systems having been published within that period. The older systems were chiefly founded on orthography, the ordinary spelling of words being represented simply by a set of more convenient symbols for letters. The highest brevity attainable in this way was, however, altogether insufficient for reporting; and consequently, arbitrary signs for words and phrases, and distinctions in the value of characters, dependent on their relative position on, above, or below the line of writing, were largely used. The more modern systems have all been to a greater or less extent *phonetic*, or representative of sounds instead of letters, the number of sounds into which syllables may be resolved, being considerably smaller than that of orthographic elements.

Of the two classes of elements, vowels and consonants, the latter are the more important for the recognition of words; and these are generally written without lifting the pen, vowels being supplied by dots and other interpolated symbols. In some systems, no attempt is made to discriminate one vowel from another, but only the places where vowels occur are indicated by a general sign; in others, the five vowel letters have distinctive symbols; and in others an accurate representation of the varieties of vowel sound is aimed at. The degree in which words are recognisable without vowels, may be judged of by the following specimen:

Chmbrzz nsclpd a dcshnr v nvrsl nlj fr th ppl n th bss v th ltst dshn v th jrmn cnvrsshnz lcscn.



An indication of *where* vowel sounds occur—without shewing *what* vowels—will be found to give increased and sufficient legibility to a reader who is acquainted with the language. Thus:

Ch-mb-rz-z -ns-cl-p-d- - a d-csh-n-r- -v -n-v-rs-l n-l-j f-r th- p-pl -n th- b-s-s -v th- l-t-st -d-sh-n -v th- j-rm-n c-nv-rs-sh-nz l-cs-c-n.

Chambers's Encyclopædia, a Dictionary of Universal Knowledge for the People, on the basis of the latest edition of the German Conversations Lexicon.

Shorthand alphabets consist of simple straight and curved lines, to which hooks, loops, or rings are added. These elements of writing are common to all systems, but the powers associated with the symbols are, of course, different in different systems. Much ingenuity has been shewn by various authors in developing the application of the simple radial and segmental lines of a circle, and the positions of a dot, for the representation of language; but, in many cases, while a wonderful amount of apparent brevity has been attained—as by writing on a staff of lines, each of which gives a different value to the same sign—the systems are all but impracticable, from the multitude of details with which the memory of the learner has to be burdened. The prevailing fault of such systems of shorthand is, that they are long in being short. Reporters *must* abbreviate even the simplest possible form of alphabetic writing, but the mastery of a shorthand alphabet for other than reporting purposes, is a very easy matter; and the acquisition will be found valuable, in enabling a writer to save four out of every five motions of the pen, in private memoranda, correspondence, &c.

A great impetus was given to the study of shorthand, about 25 years ago, by the publication of Mr Isaac Pitman's *Phonography.* The introduction of the penny postage, at the same period, vastly aided the diffusion of the system, and societies for phonographic correspondence were established in all parts of the kingdom. The Psalms, the New Testament, and many other works, were published in the phonographic alphabet, and magazines written in shorthand found a widely-diffused circle of supporters. This system of writing is elegant and expeditious to a practised hand, and a very great improvement on all preceding systems. The alphabet consists of the following characters:

The distinction between *breath* and *voice* (or *mute* and *sonant*) consonants, as above shewn, is happily expressed by a thickening of the symbolic line for the latter elements. The characters in the second column are, however, anomalous, the first four, which are written 'thin,' representing voice consonants, and the fourth and fifth, written with the difference only of 'thick' and 'thin,' representing distinct formations, which differ from each other as *d* does from *g*, and both of which are voice consonants.

In this system vowels are denoted by the interpolated signs—

placed at the top, the middle, or the bottom of the consonant lines. The vowel marks are written *thick* for 'long,' and *thin* for 'short' sounds. The long and short vowels are not, however, phonetic pairs, differing only in quantity; and thus the vowel scheme is less accurate than that of the consonants. It is, besides, very complex to a beginner, from the employment of a special set of characters for vowels preceded by *w* and *y*, the latter elements not being included in the alphabet of consonants.

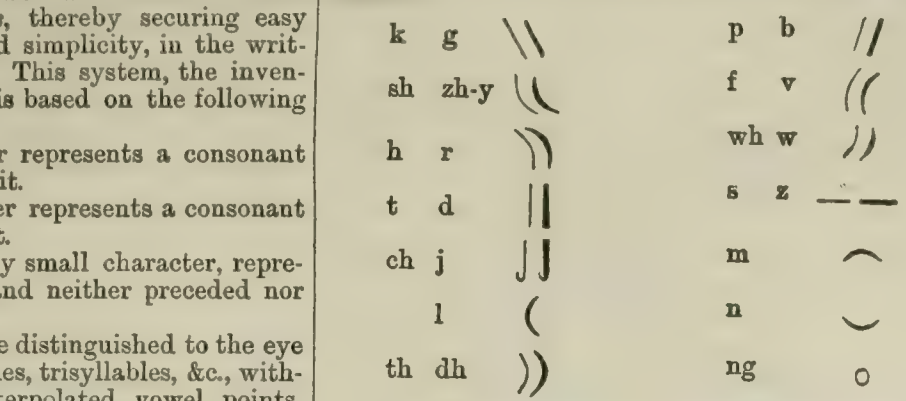
In 'Phonography,' as in almost all other systems of shorthand, vowels are added by separate liftings of the pen, while their insertion is indispensable to legibility, unless special modes of writing consonant combinations are adopted. The latter expedient is employed by Mr Pitman for such compounds as *pr*, *pl*, *spr*, *str*, *nl*, *mp*, &c., the characters for which make, practically, large additions to the alphabet. The use of a general vowel sign would evidently be of little advantage in this system, as it would, equally with the exact vowel marks, require the pen to be lifted for its insertion.

In a more recent system of phonetic shorthand, a

new principle of writing is adopted, by which the positions of all sounded vowels are indicated in the writing of the *consonants*, thereby securing easy legibility, with brevity and simplicity, in the writing of a *known* language. This system, the invention of Mr Melville Bell, is based on the following principles:

I. A full-sized character represents a consonant with a vowel sound *before* it.

II. A half-sized character represents a consonant with a vowel sound *after* it.



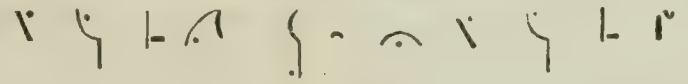
III. A tick-sized, or very small character, represents a consonant *alone*, and neither preceded nor followed by a vowel.

In this way, all words are distinguished to the eye as monosyllables, dissyllables, trisyllables, &c., without any necessity for interpolated vowel points. The relative size of the letters *pt*, for example, forming the consonant outline of the words *pet*, *apt*, *pity*, *poet*, &c., shews the first pair of these words to be monosyllables, and the others to be dissyllables. Thus:

pet, . . tick *p*, full *t*. *apt*, . full *p*, tick *t*.	one syllable.
pity, . half *p*, half *t*. *poet*, . half *p*, full *t*. *attack*, . full *t*, full *k*. *active*, full *k*, tick *t*, full *v*.	two syllables.
capital, half *k*, half *p*, tick *t*, full *l*. *appetite*, full *p*, full *t*, full *t*.	three syllables.

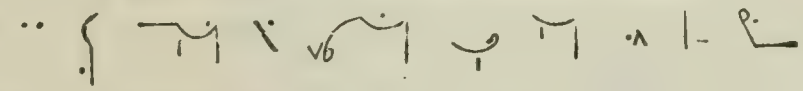
The importance of this mode of writing will be at once obvious in such words as contain the same consonants with various syllabication, as *sport*, *sprite*, *spirit*, *support*, *separate*, *aspirate*, &c.

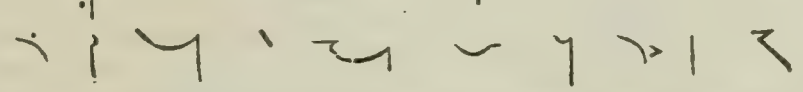
To a learner this system offers a very brief and easily read stenography of his own language, so soon as he has learned the alphabet only. The system is of course susceptible of the ordinary methods of abbreviation for the fleet exigencies of the reporter, such as the use of letters for words, special positions for 'logograms,' &c. Exact vowel marks also are provided for insertion wherever they are considered necessary, as in the writing of foreign words, proper names, &c. The following is Mr Bell's alphabet, as published in the *Reporter's Manual:*



In this arrangement, *all* breath consonants are written by thin lines, and all voice consonants by thick lines; and no additional characters are used for compound consonants. The essential principle of the system, by which the positions of vowels, or the absence of vowels, are indicated in the writing of the consonants, manifestly dispenses with the necessity for separate symbols for combinations.

The three different sizes of the alphabetic characters, which express the effect of vowels in this system, are employed with some specific value in all systems. In Mr Pitman's *Phonography*, for instance, 'half-sized' consonants are used to denote the addition of *t* or *d* to the consonant which is written; while the *vowel* symbols are in size precisely the same as the characters which, in Mr Bell's phonetic shorthand, represent 'tick-sized' consonants.



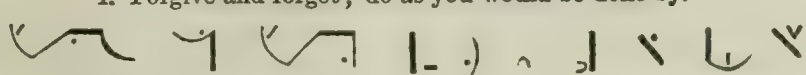


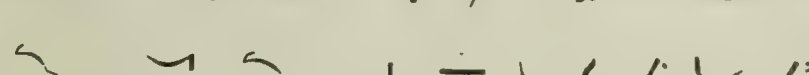
The vowel scheme of the latter system furnishes a separate sign for every difference of vowel quality, and the distinction of thick and thin symbols is limited to actual phonetic pairs of long and short sounds, such as are heard in the words *full* and *fool*, *yon* and *yawn*. But, except in monosyllables written in the first or simply alphabetic style, the distinctive vowel signs rarely require to be inserted.

As an illustration of the aspect of the writing in these two phonetic systems, the following sentences are written in the full alphabetic styles:

1. Be fit to live that you may be fit to die.

1. PITMAN. 
BELL. 





2. He that cannot be silent knows not how to speak.

2. PITMAN. 
BELL. 

3. Where words are scarce they are seldom spent in vain.

3. PITMAN. 
BELL. 

4. Forgive and forget; do as you would be done by.

4. PITMAN. 
BELL. 

The fundamental difference between these systems will be understood from the examples; in the first system, all syllabic sounds are definitely shewn by means of vowel points, but without these latter, a reader could not distinguish the number of syllables contained in a word; in the second system, the consonant outline, without inserted vowels, informs the eye of the number of syllables in every word—all full as well as all half-sized consonants being necessarily syllabic.

Some systems of shorthand consist mainly of ideographic signs, alphabetic writing being used only as supplementary to the arrangement of arbitrary symbols and ruled lines. Thus the positions *upon*, *above*, or *below* a single line, are associated with such meanings as *present*, *past*, and *future* for verbs; *affirmative*, *interrogative*, and *negative* for propositions; *personal*, *relative*, and *demonstrative* for pronouns, &c.; while the symbols for the various classes of words are merely uniform points, commas, hyphens, and other non-alphabetic marks. Sometimes the principle of different positional values of symbols is carried to so great an extent, that the projectors of such systems are able to boast, paradoxically, that one-half of any speech is virtually written before the speaker opens his lips! Reporters have discovered several objections to Pitman's method, most of which, it is said, are obviated by the Tachygraphy of D. P. Lindsley, of Mendon, Massachusetts, which experts declare is more easily read. Lindsley's Tachygraphy is described as purely phonetic, and uses the simplest geometrical lines so arranged as to insure a *linear* direction, and not a *perpendicular* style of writing, while a word can be written without raising a pen. Mr Lindsley has, as said Horace Mann, 'phonographied Phonography,' so that it really appears to be an attainable art. The following specimen of 'dot' positions is extracted from Moat's *Shorthand Standard:*

Moat's system may be taken as the representative of this class. It is certainly the most elaborate and methodical—in fact, a marvel of ingenuity and perseverance—but, like other ideographic systems, it is so burdensome to the memory of a learner, as well as difficult in application, that it could never be of much use to any other person than the contriver.

In all systems, more or less use is made of what may be called analogical symbols, such as a *circle*, for the *earth*, the *world*, &c., with a point *above*, *below*, *before*, *after*, or *within* the circle, for such phrases as *above the earth*, *under the earth*, *in the world*, &c. But alphabetic writing by sound can derive little assistance from such arbitrary signs, however suggestive. Abbreviated phonetic writing undoubtedly furnishes the simplest and most exact method of stenography; and the two systems above exemplified, sufficiently illustrate the nature of the art of shorthand, as most widely practised on the phonetic basis at the present day.

The older methods of Byrom, Taylor, Gurney, Lewis, Odell, and other authors, still find many adherents. In fact, any system to which a writer is accustomed is better than longhand; and, practically, reporters and others modify for themselves, to a great extent, the systems they employ. Fancutt's *Stenography on the Basis of Grammar* (1840) may be referred to as a very ingenious work. Jones's *Phonography* (1865), a modification of Pitman's, is one of the more recent publications on the subject. A *History of Shorthand*, containing a chronological enumeration of authors, was published a few years ago.

SHORT-SIGHT. See SIGHT, EFFECTS OF.

SHOT is the term applied to all solid balls fired from any sort of firearms; those for cannon and carronades being of iron, those for small-arms, of lead. The latter are known as bullets and small-shot. The shot used for guns at present vary from the 3-pounder, for boat and mountain artillery, to the 10½-inch shot, which weighs about 150 lbs. as a sphere, or 300 lbs. as an elongated bolt. Generally, shot are cast. There are simple practical rules for calculating the weight from the diameter of a shot, and *vice versâ*, which are often useful in reading of artillery actions. Given the diameter in inches, to find the weight in pounds: Cube the diameter, and multiply the result by 14; reject the two right-hand figures; those remaining give the weight in pounds.—Given the weight in pounds, to find the diameter in inches: Multiply the cube-root of the weight by 1·923, and the result is the diameter of the shot in inches.

Small-shot is of various sizes, from swan-shot, nearly as large as peas, to dust-shot. It is made by dropping molten lead through a colander in rapid motion from a considerable height into water. The lead falls in small globular drops. The holes in the colanders vary in size according to the denomination of the shot, No. 0 requiring holes $\frac{1}{10}$th inch in diameter, No. 9, $\frac{1}{30}$th inch. The colanders are iron hemispheres, 10 inches in diameter, and are coated within with the *cream* or scum which is taken off the molten metal. A small portion of arsenic is melted with the lead, and the fusion in the colanders is maintained by those vessels being surrounded by burning charcoal. The discovery of the advantage attending a long fall was made in England towards the end of last century. Previously the shot had dropped from the colanders at once into the water. The lead was then so soft that the shot were flattened by the water. The fall through the air enables the lead to cool and harden before taking its plunge. The smaller sizes require less fall than the larger—100 feet suffices for sizes Nos. 4 to 9—the larger sorts demand 150 feet. The highest shot tower is at Villach in Carinthia, where there is a fall of 249 feet. After cooling, shot is sifted in successive sieves to separate the sizes. Misshapen shots are found by their inability to roll; and finally, the whole are polished by rotatory motion in small octagonal boxes, in which a little plumbago has been thrown. See also CASE-SHOT, CANISTER, GRAPE-SHOT.

SHOTTS, a small and ancient village of Lanarkshire, close to the Kirk of Shotts, about 16 miles east of Glasgow. About 3 miles to the south-east of the Kirk, modern S., or S. Proper, began to rise at the close of the last century, when the Shotts Iron Company erected their extensive iron works there. S. may be said to consist of three villages—viz., Stane, Shotts Iron Works, and Dykehead; and the district within a radius of a mile from the works—which district includes these three villages—contains about 5000 inhabitants. Valuable coal and iron-stone, peculiarly suited for the manufacture of iron, abound in the district, and 1000 hands are employed in iron-making and moulding.

SHOULDER-JOINT, THE, is a ball-and-socket joint. The bones entering into its composition are the humerus or arm-bone, and the scapula or shoulder-blade, the large globular head of the former being received into the shallow glenoid cavity of the latter, an arrangement by which extreme freedom of motion is obtained, while the apparent insecurity of the joint is guarded against by the strong ligaments and tendons which surround it, and above by

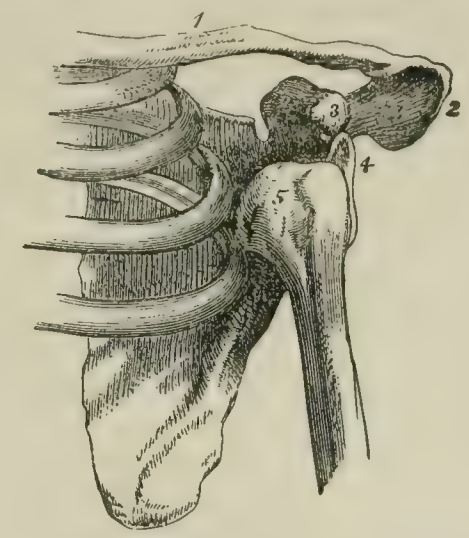
the arched vault formed by the under surface of the acromion and coracoid processes. See SCAPULA. As in movable joints generally, the articular surfaces are covered with cartilage, and there is a synovial membrane which lines the interior of the joint. The most important connecting medium between the two bones is the capsular ligament, which is a fibrinous expansion embracing the margin of the glenoid cavity above, while it is prolonged upon the tuberosities of the humerus below. From its relations with the surrounding muscles, the ligament

Fig. 1.—The left Shoulder-Joint and its Connections.
1, the clavicle or collar bone; 2, the acromion process; 3, the coracoid process; 4, the capsular ligament; 5, the coraco-humeral ligament; 6, the tendons of the biceps muscle; 7, the shaft of the humerus or arm bone; 8.the greater tuberosity of the humerus; 9, the lesser tuberosity; 10, the neck of the scapula: 11, anterior surface of the scapula.

derives much of its strength. Accordingly, in paralysis of the arm, one or two fingers can often be pressed into the joint towards the head of the glenoid cavity, from which the head of the humerus is now separated.

The shoulder-joint exhibits the following varieties of motion: 1. Flexion, to a great extent; 2. Extension, in a much more limited degree; 3. Adduction, in an oblique direction, forwards and inwards; 4. Abduction very freely; 5. Circumduction; and 6. Rotation slightly.

The morbid affections of the shoulder-joint may be divided into (1) those arising from disease, and (2) those dependent on an accident. The most common diseases are acute and chronic inflammation of the joint, which often terminate in its anchylosis or immobility. The principal accidents are fractures and dislocations. There may be fracture (1) of the acromion process, or (2) of the coracoid process, or (3) of the neck of the scapula, or (4) of the superior extremity of the humerus; or two or more of these accidents may be associated. Again, the head of the humerus may be dislocated from the glenoid cavity as the result of accident in three different directions—viz. (1), Downwards and inwards into the axilla, which is by far the most common form; (2) Forwards and inwards; and (3) Backwards on the infra-spinous fossa, or the dorsum of the scapula. The first of these varieties is of such common occurrence, that persons of ordinary intelligence should know how to recognise, and even (in an emergency) to treat it. The bones are in the position shewn in the figure; and the following are the most prominent symptoms: 'The arm is lengthened; a hollow may be felt under the acromion, where the head of the bone ought to be; the shoulder seems flattened; the elbow sticks out from the side, and cannot be made



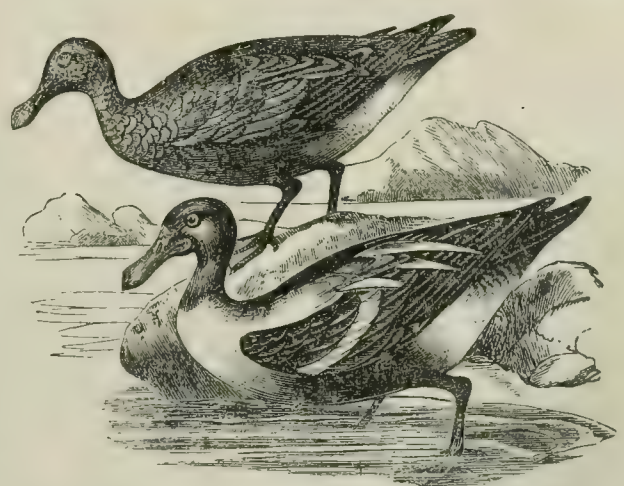


Fig. 2.—Dislocation of the Shoulder-Joint downwards.
1, the clavicle; 2, the acromion process; 3, the coracoid process; 4, the glenoid cavity; 5, the head of the humerus lying in the axilla.

to touch the ribs; and the head of the bone can be felt if the limb be raised, although such an attempt causes great pain and weakness, from the pressure exerted on the axillary plexus of nerves.'—Druitt's *Surgeon's Vade-mecum*, 8th ed. p. 282. There are at least five methods of treating this form of dislocation. It is sufficient to notice two of them. 1. Reduction by the heel in the axilla. The patient lies on a couch, and the operator sits at the edge, and puts his heel (the shoe or boot being previously removed) into the axilla, to press the head of the bone upwards and outwards, and at the same time pulls the limb downward by means of a towel fastened above the elbow. There is a figure of this operation in the article DISLOCATIONS. 2. Reduction by the knee in the axilla. The patient being seated in a chair, the surgeon places one of his knees in the axilla, resting his foot on the chair. He then puts one hand on the shoulder, to fix the scapula, and with the other depresses the elbow over his knee.—For a description of the symptoms and mode of treatment of the other forms of dislocation, and of the different varieties of practice, we must refer the reader to any systematic treatise on Surgery.

SHO'VELLER (*Rhynchaspis*), a genus of ducks,

Shoveller, male and female (*Rhynchaspis clypeata*).

of the section having no lobe or pendent membrane on the hind toe, and remarkable for the expansion

of the end of the mandibles in adult birds, particularly of the upper mandible. The lamellæ of the mandibles are long and very delicate. The legs are placed near the centre of the body, so that these birds walk much more easily than many of the ducks. The Common S. (*R. clypeata*) is smaller than the wild duck, but rather larger than the widgeon. The S. is a winter visitant in New Jersey, but not very common. A few remain in the northern states all the year. It is widely distributed over Europe, Asia, and North America. Its flesh is very highly esteemed. A species of S. is found in Australia.

SHOWERS OF FISHES have occasionally fallen in different parts of the world, exciting great astonishment. Instances of this kind have occurred in Britain. A few years since, a shower of small three-spined sticklebacks fell near Merthyr-Tydvil in Wales, sprinkling the ground and house-tops over an area of at least several square miles. They were alive when they fell; yet if caught up by a whirlwind from any of the brackish ponds near the sea, in which this species of fish abounds, they must have been conveyed through the air a distance of almost thirty miles. Another recent instance occurred at Torrens, in the isle of Mull, in which herrings were found strewed on a hill five hundred yards from the sea, and one hundred feet above it.

Showers of fishes occur much more frequently in those tropical countries where violent storms, sudden gusts of wind, and whirlwinds are most common. In India, a shower of fishes varying from a pound and a half to three pounds in weight has been known to fall. Sometimes the fishes are living, more frequently they are dead, and sometimes dry or putrefying. They are always of kinds abundant in the sea or fresh waters of the neighbourhood; and it cannot be doubted that they are carried up into the air by violent winds or whirlwinds; although they sometimes fall at a considerable distance from any water which could supply them. The sudden reappearance of fresh-water fishes in ponds which have been dried up for months in tropical countries, is often popularly ascribed to their falling from the clouds; but the truth is, that they have been buried in the mud below, existing probably in a state analogous to that of animals in cold climates during hybernation. A pool, the bottom of which has long been dry, and on which grass has grown and cattle have walked, is again filled with fishes in a few hours after it is filled with water.

SHRA'PNELL SHELL. See SHELL.

SHREW (*Sorex*), a genus of small quadrupeds of the family *Sorecidæ*. They are often popularly confounded with mice and rats, but are really very different, having insectivorous and not rodent teeth. The head is very long; the snout elongated, attenuated, and capable of being moved about; the eyes small; the tail long; both body and tail covered with fine short hair; the feet have a broad sole and 5 toes. The genus has recently been subdivided, and the British species belong to more than one of the subdivisions. The COMMON S. of Britain (*S.* or *Corsira vulgaris*) was, until recently, confounded with *S. araneus*, a species common in continental Europe. It is nearly 2½ inches in length from the snout to the root of the tail, the length of which is about 1¾ inches. It abounds in dry fields, gardens, and hedge-banks; feeding chiefly on insects and worms, for which it grubs with its long snout amongst the roots of the herbage. It burrows, and makes long *runs* just under the surface of the ground. It is an excessively pugnacious little animal, and the males have fierce combats in spring, in which many are killed. Cats kill the S., but do not often eat it, probably on account of its strong musky smell; but it is the prey of weasels, hawks, owls, and shrikes. Harmless and inoffensive as it is, it has long been very generally regarded with

Common Shrew (*Sorex vulgaris*).

dread and aversion by the vulgar. (See White's *Natural History of Selborne*).—The WATER S. (*Neosorex albibarbis*) is larger than the Common S., being fully 3 inches long, and the tail 2 inches. It is of a blackish-brown colour, gray or white on the underparts. It burrows in the banks of streams, and is very aquatic in its habits. It is found in the northern United States.—Some of the Indian species of S. attain a much larger size, as that called the Musk Rat (q. v.). There is an Italian species which is the smallest of all known Mammalia. It is only about 1½ inch in length, exclusive of the tail, which measures about 1 inch.

SHREW MOLE (*Scalops*), a genus of insectivorous Mammalia, of the family *Talpidæ*, and very nearly allied to the moles. There are 6 incisors, 2 canine teeth, 8 false molars, and 6 true molars in each jaw. The ear is destitute of auricle; the eyes are very small, and much concealed; the feet are 5-toed, the fore-feet large, as in the mole. The whole figure, and also the habits, resemble those of the mole.—There are several species, all natives of North America.

SHREW'SBURY, a parliamentary and municipal borough and market-town, the capital of Shropshire, stands on the Severn, by which it is nearly surrounded, 163 miles north-north-west of London by the London and North-western Railway. It is irregular in plan, contains many inferior houses, partly built of timber, but often of very picturesque appearance. In the modern quarters, the houses are handsome and regular. Two bridges, the 'English' and the 'Welsh,' cross the Severn, and connect the town with the suburbs of Abbey-Foregate and Coleham on the east, and Frankwell on the west. To the north, is the other suburb of Castle-Foregate. The town contains interesting remains of the ancient walls, the castle, two monasteries, and a Benedictine abbey. The remains of the Abbey Church now form the church of Holy Cross. There are other ecclesiastical edifices, a Free School, with an income from endowment of £3100 a year, and 22 exhibitions to the universities; a number of other important schools, institutes, hospitals, &c. The Town and County Hall, the Public Rooms, a handsome Greek structure, and the Market-house, dating from the reign of Elizabeth, are worthy of mention. S. carries on manufactures of linen-thread, canvas, and ironwares, and there is a salmon-fishery on the Severn. The Brawn and 'Shrewsbury Cakes' made here have long been held in esteem. The borough returns two members to the House of Commons. Pop. (1861) 25,803.

Vol. VIII., page 697.

SHRIKE

S., called by the Welsh Pengwern, was named by the Anglo-Saxons *Scrobbes-Byrig*, and of this the modern name is a corruption. The town connects itself intimately with the history of the country from the 12th to the 17th century. It was taken by Llewellyn the Great, Prince of North Wales, in 1215, during the disturbances between King John and the barons; and in 1403, Henry IV. here defeated the insurgent Percies and their allies with great slaughter. It was taken by the Parliamentarians in 1644.

SHRIKE, or BUTCHER-BIRD (*Lanius*), a genus of birds of the family *Laniadæ* (q. v.), imitating in its bill the *Falconidæ* more nearly than any other of that family; having a short, thick, and compressed bill, the upper mandible curved, hooked at the tip, and furnished with a prominent tooth, the base of the bill beset with hairs, which point forwards. The species are numerous, most of them natives of warm climates, although some occur in the more northern parts of the world. They prey

Great Gray Shrike (*Lanius excubitor*).

on insects and small birds, and have a remarkable habit of impaling their prey on thorns; so that the nest of a S. may be discovered by the numerous insects impaled in the neighbourhood of it. Shrikes kill and impale many insects which they never eat, leaving them to dry in the sun; and in confinement they make use for this purpose of a nail, if provided with it, or stick portions of their food between the wires of the cage. They can imitate in some degree the notes of many birds, particularly those which are the utterance of distress, and they seem to make use of this power in order to attract birds within their reach. The most common British species, rarely seen, however, except in the south of England, is the RED-BACKED S. (*L. colluris*), a bird only about 7½ inches in length, about a third of the length being formed by the tail, which is square at the end. Insects are the chief food of this bird, but it also preys on small birds, young frogs, and even young pheasants.—The GREAT GRAY S., or SENTINEL S. (*L. excubitor*), is about the size of a thrush. It is a rare bird in Britain, but common in some parts of Europe, and is found also in Asia and North America. It was formerly used by falconers in catching hawks, of which it is greatly afraid, screaming loudly on their approach: the falconer waited in concealment, after fastening some pigeons and a S. to the ground, until the scream of the S. gave him notice to pull the string of his net.

SHRIMP (*Crangon*), a genus of crustaceans, of the order *Decapoda*, suborder *Macroura*, and family *Crangonidæ*, allied to lobsters, crayfish, and prawns. The form is elongated, tapering, and arched as if hunch-backed. The claws are not large, the fixed finger merely a small tooth, the movable finger hook-shaped. The beak is very short, affording a ready distinction from prawns. The whole structure is very delicate, almost translucent; and the colours are such that the creature may readily escape observation, whether resting on a sandy bottom, or swimming through the water. The quick darting movements of shrimps, like short leaps, however, betray them to any one who looks attentively into a pool left by the retiring tide on a sandy shore. When alarmed, they bury themselves in the sand, by a peculiar movement of their fanlike tail fin.—The COMMON S. (*C. vulgaris*) is very abundant on the British coasts, and very generally elsewhere on those of Europe, wherever the shore is sandy. It is about two inches long, of a greenish-gray colour, dotted with brown. It is in great esteem as an article of food, and is generally taken by nets in the form of a wide-mouthed bag, stretched by means of a short cross-beam at the end of a pole, and pushed along by the shrimper wading to the knees. Sometimes a net of larger size is dragged along by two boats. The supply of the market with shrimps affords employment to a great number of people.—The other species of S. seem to be equally fit for the table. Several are occasionally taken on the British coasts, but belong rather to more southern climates. Shrimps are very interesting inmates of the aquarium.

SHRO'PSHIRE, or SA'LOP, a frontier county in the west of England, bounded on the W. by North Wales, and on the E. by the counties of Stafford and Worcester. Area, 826,055 acres; pop. (1861) 240,959. The Severn, the principal river, enters the county from Montgomeryshire, about 12 miles west of Shrewsbury. It pursues a generally south-east course of 70 miles across the county, is navigable throughout, and is joined by two considerable tributaries, the Tern and Teme. To the north and north-east of the Severn, the county is generally level, and is under tillage; to the south and south-east, it is hilly and mountainous, and here cattle-breeding is extensively carried on. A breed of horned sheep is peculiar to this county. More than three-fourths of the whole acreage are arable, or in pasture and meadow. The soil is generally fertile and well cultivated, though there are still extensive tracts of waste land. S. is remarkable for its mineral wealth. The coal, iron, copper, and lead fields of Coalbrookdale, Snedshill, Ketly, &c., are very productive. Several thousand persons are employed in raising coal, iron, stone, and lime, and in the iron manufacture. The county returns four members to the House of Commons. Capital, Shrewsbury.

SHROUDS are very strong ropes passing from the heads of the lower masts in a ship to the chains or channels on her sides, for the purpose of affording lateral support. They are crossed by thinner ropes, called ratlines, to form steps or ladders. The top-mast shrouds in ship-rigged vessels are similar, except that they terminate in a row of dead-eyes on the outside of the tops.

SHRO'VETIDE (Anglo-Saxon *scrifan*, to shrive, to confess) literally means 'confession-time,' and is the name given to the days immediately preceding Ash-Wednesday, which, as indeed the whole period after Septuagesima Sunday appears to have been, were anciently days of preparation for the penitential time of Lent; the chief part of which preparation consisted in receiving the sacrament of penance, i. e., in 'being shriven,' or confessing. In the modern discipline of the Roman Catholic Church a trace of this is still preserved, as, in many countries, the time of the confession, which precedes the

paschal or Easter communion, commences from Shrovetide. These days were sometimes called Fasting-tide or Fast-mass, names which are still retained among the population in some parts of Great Britain. The name of S. was retained in England after the Reformation, although the practice of 'shriving,' in which it had its origin, was abandoned. The precept of 'shriving' having been fulfilled, the faithful, upon the eve of entering upon the Lent, were indulged with permission to give themselves up to amusements, and to festive celebrations, of which the counterpart is still seen in the continental carnival. In England, the pastimes of football, cock-fighting, bull-baiting, &c., were, down to a late period, recognised usages of S.; and the festive banquets of the day are still represented by the pancakes and fritters from which Pancake Tuesday took its name, and by the 'collops' which gave its title to Collop Monday. These usages are gradually disappearing.

SHRUB (see SYRUP), a kind of liqueur made chiefly in the West Indies. It consists of lime or lemon-juice and syrup, to which a small portion of rum is added; other flavouring materials are used occasionally.

SHRUBS are plants with woody stem and branches like trees, but of smaller size, not generally exceeding 20 feet in height, and branching near the root, so as to have no main stem of considerable height. When a shrub is of small size and much branched, it is often called a *bush*. There is no more important botanical distinction between trees and shrubs, and the same genus very often includes species of both kinds. Many shrubs, as honeysuckle, are climbers.

In point of Law, whoever plants a shrub thereby makes it part of the soil, and it becomes a kind of fixture, incapable of being removed by tenants. But if the tenant is a nurseryman, who makes a business of planting and removing shrubs, it is otherwise. Whoever unlawfully and maliciously cuts, breaks, barks, or roots up a shrub growing in a pleasure-ground, garden, or ground adjoining a dwelling-house, if the injury exceed one pound in value, is guilty of felony, and liable to penal servitude for three years; and wherever the shrub is situated, if the damage amount to one shilling, the person is liable to be imprisoned or fined by a justice of the peace.

SHUGSHU'T, a small town of Turkey in Asia, in Anatolia, on the left bank of the Sakaria, 95 miles in direct line south-east of Constantinople. On an adjacent hill is the tomb of Othman (q. v.), founder of the Ottoman dynasty. The tomb, resembling the handsomest and most ancient of the Turkish sepulchres at Constantinople, stands amid a grove of cypresses and evergreen oaks. Pop. estimated at about 5000.

SHUMALA'RI. See HIMÂLAYA.

SHU'MLA, a strongly fortified city of Bulgaria, European Turkey, stands on the Little Balkan, 50 miles west of Varna, and 60 miles south-south-west of Silistria. It is bounded on the north and west by mountains, and on the south and east by an undulating plain furrowed by valleys that extend north to the Danube. Its situation is pleasing, and the character and distribution of its buildings give it a picturesque appearance. The roads from the Turkish fortresses on the Lower Danube and in the Dobrudscha on the north, and from the passes of the Eastern Balkan on the south, converge upon S., and for this reason it is an important strategic position. It contains an arsenal, military hospital, large barracks, a citadel occupying a height, and surrounded with high and thick walls; and in 1853, on the outbreak of the war with Russia, its fortifications were greatly extended. In the vicinity is an intrenched camp in a position of great natural strength, which can accommodate from 40,000 to 60,000 men. The more accessible approaches to the town are guarded by forts. The culture of wine and grain, and the rearing of silk-worms, are the chief employments; and the town is famous for its manufactures of copper and tin wares, ready-made clothes, and leather. Pop. 30,000, exclusive of the garrison. The Russians attacked the town in vain on three separate occasions—in 1774, in 1810, and in 1828.

SHUNT SYSTEM OF RIFLING is a very ingenious arrangement for securing the accurate centring of a projectile discharged from a rifled cannon. To obtain precision of aim and range, it is absolutely essential that the axis of a projectile should, at the moment of discharge, coincide exactly with the axis of the bore. This can scarcely be obtained unless the shot fits with extreme tightness into the gun; and if it does so, and the gun is a muzzle-loader, it is scarcely possible to load it. The ordinary principle has the projectile smaller than the bore, so as to pass readily into the gun, resting, of course, on the bottom of the bore. The projectile is covered with a soft metal, as lead, which expands with the pressure behind, and fits the shot tight into the grooves; but from the fact that it rested (at the commencement of the expansion) on the bottom of the bore, the axis of the shot is always below the axis of the bore. To obviate this, Sir William Armstrong designed the 'shunt' system, which in practice has been found admirably effective. In rifling the gun, the groove for 14 inches from the muzzle consists of a wide, deep indentation (*b* in figs. 1 and 2), and at the side of it a narrow indentation of less depth, *a*; from 14 inches to 22 inches from the muzzle, this narrow groove gradually deepens, till it attains the level of the broad groove, after which they run together for a short distance, until a shunt at *c*, fig. 2, narrows

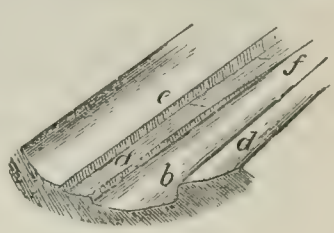

Fig. 1.

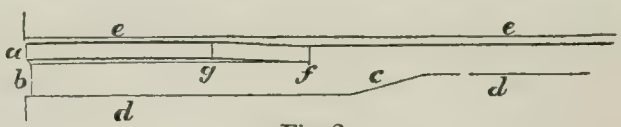

Fig. 2.

the whole groove on the same side as *a* to the original width of *b*. Projecting from the shell (fig. 3) is an iron flange *a*, too high to pass the narrow groove, and still higher, by its side, a narrow band of zinc or of brass studs, *b*. Each of these passes freely along the broad deep groove of the bore. As the shot is rammed home, the twist of the rifling brings the iron flange against the edge *d* (figs. 1 and 2) of the broad deep groove, which enables both the flange and zinc band to pass freely until past *f* (fig. 2), where the inclined plane ends. At *c*, however, where the groove becomes narrowed to only the width of the flange and band together, the shot is shunted over to the left. In this position it is rammed home. In coming out, of course, the

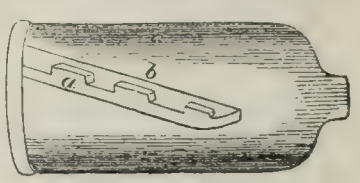

Fig. 3.

pressure of the twist is reversed, and the zinc band presses against the straight edge *e*; on reaching *f*, the force of the exploded powder behind drives the shot on, while the inclined groove from *f* to *g* flattens down the zinc band, so that the projectile ceases to lie on the bottom of the bore, and is firmly centred by its several bands on the shallow grooves (whatever their number may be) round the bore's circumference. The lead fitting at the back of the shot has been meanwhile driven by the explosion into the deep wide grooves, so as to stop windage.

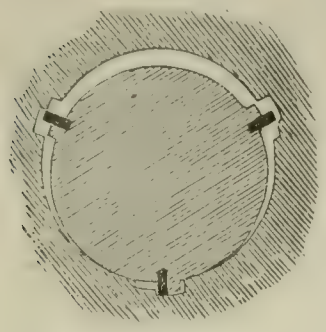

Fig. 4.—Going in.

The Russians have a shunt system borrowed from Sir W. Armstrong's, but differing in details. American guns, on similar principles, have been made experimentally. The invention does not appear to have been yet applied to small-arms.

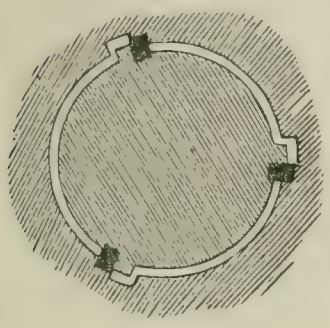

Fig. 5.—Coming out.

The sections of the muzzle in this article, figs. 4 and 5, are necessarily exaggerated in regard to the position of the shot, to shew the principle. In reality, there is only a minute difference between the diameters of bore and projectile.

SHU'SHA, a fortified town of Russian Transcaucasia, in the government of Elizabethpol, and 120 miles south-west of the town of Shemakha. It occupies a strong position on a mountain, accessible only on one side, and contains upwards of 19,000 inhabitants.

SHU'STER, a city of Persia, in Khuzistan, on the Karun, 30 miles east-south-east of Dizful, at the foot of a range of sandstone hills. In the early part of the present century, it was an important town and the capital of the province; but it was nearly depopulated by an epidemic in 1832, and was much damaged by an inundation in 1840. On a height stands the castle, commanded, however, by a loftier elevation. The walls have been allowed to fall, and a fourth part of the town is in ruins. Customs are collected here, but the trade is not extensive. Pop. about 25,000.

SHUTTLE, the instrument used to carry the weft-thread in weaving. See LOOM.

SIA'LOGOGUES are substances which, by local stimulating action, increase the secretion of Saliva (q. v.). Amongst the substances which thus act as direct stimulants to the salivary glands, we may especially mention Horse-radish root, Mezereon bark, and Pellitory root. Horse-radish root, when chewed, produces a copious flow of saliva, and has been found useful in aiding deglutition in cases of paralysis of the tongue. If Mezereon bark is used in the same way, the saliva should be frequently ejected, in consequence of the acrid properties which it absorbs from the drug. Pellitory root is the best of this class of remedies. Fragments weighing from half a drachm to a drachm may be frequently chewed when we wish to increase the flow of saliva in cases of facial neuralgia, rheumatism of the muscles of mastication, and paralysis of the tongue.

SIA'M (native name *Thái* = the Free, or *Muang Thái* = the Kingdom of the Free), the chief state of Indo-China, is bounded on the S. by the Gulf of Siam and the Malay Peninsula. On the W., N., and E., the frontier-line is ill-defined and fluctuating, owing to many tribes being only partially under subjection, and to the constant wars of aggrandisement between S. and the Malayan and Burmese races on the west, and the Cambodian and Cochin-Chinese races on the east. According to a recent account, the country lies in lat. 4°—21° N., long. 96°—102° E.; is 1200 miles in length, and about 350 miles in extreme breadth. Area estimated at from 190,000 to 290,000 sq. m.; pop. stated at from 5,000,000 to 6,300,000. The kingdom consists of 41 provinces, each governed by a Phaja, or functionary of the highest rank. There are numerous districts beyond the limits of the kingdom proper, as the Laos, Malayan, and Cambodian dependencies, which are more or less under subjection to S., and pay tribute generally once in three years. S. itself pays tribute to China, but only as a matter of usage and convenience, for it receives from that country more than a return, in the remission of duties upon Siamese vessels bound to Chinese ports. Cambodia is situated between S. on the west and Cochin-China, and as sovereignty over it is claimed by both these countries, and as it is too feeble to resist the claims, it pays tribute to both.

Surface, Hydrography, Coast-line, Soil, and Climate.—The mountains which cover the northern districts of the country, and form natural barriers along its east and west frontiers, are branches of the great system of the Himalaya. Though the northern dependencies of S. are mountainous, the kingdom proper is a vast plain, which only becomes hilly on its northern frontier. The great river of the country, the Nile of S., is called by foreigners Menam, or more commonly, Meinam; but the Siamese call all rivers by this name, and distinguish the river by adding to the name Menam the name of the chief town or village on its banks; thus, Menam Bangkok is the river of Bangkok, that is, the great river of the country, which Europeans and other foreigners have agreed to call Meinam. This river, the great life-sustaining artery of the country, rises among the mountains of the Chinese province of Yunnan, whence it flows south, and after a course of more than 800 miles in this direction, throws itself by three mouths, which are from 6 to 8 fathoms deep, into the Gulf of Siam, about 30 miles (18 miles in direct line) below Bangkok. It receives a number of important affluents, notably the river Phitsalok, which joins it in lat. about 17° 35′ N. The annual inundation of the Meinam, the occasional non-occurrence of which entails failure on a great portion of the rice-crops, commences in June, and ends in November. Impregnated with the rich soil which it brings from the interior, its waters, in August, overflow the banks to a height sometimes exceeding six feet above the ordinary level. The tract of country within the direct influence of the inundations is estimated at 12,000 sq. m.; but, properly speaking, the actual valley of the Meinam, commencing 450 miles above the mouth of that river, and with an average breadth of 50 miles, has an area of upwards of 22,000 sq. m., and forms a tract of country the fertility of which is not exceeded in any other quarter of the globe. Of the other great rivers, the chief is the Mei-kong, which flows through the eastern districts of the empire, and is said to be 1600 miles long. The coast-line, fringing the edge of the Gulf of Siam, may be roughly estimated at 1100 miles, exclusive of minor windings.

The principal ports on the coast-line are Paknam (pop. 6500), defended by three forts; Paklat, a few miles above Paknam (pop. 7000), defended by a fort on each side of the river; Meklong, at the mouth of the river of the same name, long. 100° 10′ E., a beautiful city, with floating bazaars, fine pagodas and gardens, and a pop. of 10,000; Chantaburi, long. about 103° E., near the mouth of a river which, though short, fertilises with its inundations a considerable district, a place of active trade with China and Cochin-China, with a pop. of 6000; and Bangplasoi, 27 miles east-south-east of Paknam, engaged in a profitable fishery and in agriculture, pop. 6000. The breadth of the Malayan Peninsula, in lat. 11° N., is only 50 miles, and here two streams, the one flowing west to the Bay of Bengal, and the other east to the Gulf of Siam, offer great facilities for the construction of a ship-canal, for their sources being near each other, a few miles of canalisation are all that would be required to connect them, and thus form a sea-way across the peninsula, which would shorten the voyage between India and Eastern Asia by many days, and often by weeks.—The climate of S. is, for a tropical region, salubrious; the resident missionaries speak highly in its favour. The mean temperature at Bangkok, for a series of eight years, was 81° 14′; the maximum heat, within the same space, was 97°, and the minimum 54°. Hurricanes and typhoons are almost unknown in S., though it is visited every year by the south-west and north-east monsoons—the former bringing clouds, thunder-storms, and rain, the latter bringing refreshing weather.

Agriculture, Flora, and Fauna.—In S., few of the instruments in use in scientific agriculture are known, and in many parts of the country, in 1855, the ground was prepared for the seed by turning herds of buffaloes into the fields to trample down the weeds and move the soil, and afterwards by harrowing the ground with thorny shrubs. But the soil here is so rich that the smallest outlay of capital and labour is rewarded by abundant harvests. A much more advanced system of agriculture, however, has been introduced within recent years, and the quantity of agricultural products exported has greatly increased. Rice and sugar are the principal crops. Of the other products, the chief are *Aquila*, or eagle-wood, renowned for its perfume, and extensively used on that account at funerals, marriages, and other ceremonies in Eastern Asia; gutta-percha; cardamoms; gamboge; bamboo; the rattan; valuable palms; the guava; mango; daurien, esteemed the king of fruits in S.; the mangosteen, and many other fruit and other trees, including teak and a variety of valuable ship and house timbers. Among the animals, the most famous is the elephant, which abounds in the forests. It is against the law of S. to kill elephants, as these animals are considered the property of the king; but many of them are nevertheless slain for the sake of their tusks. A variety of this animal, said to be peculiar to S., is the white elephant, which is not really white, but of a light mahogany colour. This animal is held in the highest veneration, the cause of which is, that he is 'supposed to be the incarnation of some future Buddha, and will therefore bring blessings on the country which possesses so great a treasure.' He is fed upon fresh grass, and sugar-canes and plantains, served in rich dishes, is covered with ornaments, inhabits a building attached to the palace, enjoys the rank of nobility, and is tended by a staff of officers, guards, valets, &c. Tigers abound, especially in the Laos country in the north; tiger-cats, rhinoceroses, boars, wild pigs, elks, and deer of many kinds, tenant the woods. Crocodiles, lizards, and serpents of various kinds are numerous. Excellent fish are found on the coasts and in the rivers.

Minerals.—Gold is found among the mountains, and silver in combination with other metals; copper, tin, lead, and iron are abundant, and are extensively worked by the Chinese. Precious stones are found in great number and variety.

Manufactures.—Vases, urns, and other vessels, in the manufacture of which gold is embossed upon silver, are made here in great numbers, and have an oriental celebrity. Gold-beating, iron-founding, and manufactures of fine cloth, glass wares, and pottery are carried on.

Commerce, Exports and Imports.—In former times, Bangkok (q. v.) was the most commercial city east of the Cape of Good Hope, after Calcutta and Canton, and 60 British ships were engaged in trade with the river Meinam. But in 1855, such had been the influence of bad legislation, and such the destructive progress of monopoly, that the foreign trade had become reduced almost to nothing. Sir John Bowring, Her Majesty's Plenipotentiary, arriving in S., negotiated a treaty of friendship and commerce with the Siamese rulers (signed at Bangkok, April 1855), which provides that British subjects are permitted to trade freely in all the seaports of S., may purchase lands, houses, &c., and may profess the Christian religion undisturbed. By this treaty, all monopolies are rescinded, British traders purchasing directly from the producer, and selling directly to the purchaser, without the interference of any third party. Export duties are levied upon all goods that leave the country, but they pay one impost only, whether this be levied under the name of inland-tax, transit-duty, or duty on exportation. Prior to 1856, when the treaty first took effect, the British arrivals (including Mussulman vessels under the British flag) amounted to only 12 per annum; in 1858, they amounted to 81 vessels; and in 1863, the entries were 82 vessels, of 30,363 tons, and the clearances 78 vessels, of 28,603 tons. In 1868, 408 vessels of all nations (not including junks), of 200,064 tons, entered and cleared the port of Bangkok. In the same year, the exports amounted to $2,076,842. In 1865 the principal exports were rice, 36,718 piculs (the picul = 133⅓ lbs.); sugar, 81,966 piculs; and large quantities of stick-lac, hides, salt, pepper, sapan wood, and the other products and manufactures of the country, including a small quantity of cotton. These statistics are for the port of Bangkok alone. The revenue of the king is estimated at about $15,000,000, about five-sixths of which is raised by direct taxation, or poll-tax, the remainder from vassal princes and sale of privileges.

Inhabitants and Government.—The Siamese proper, that is, the Thái race, form about a third of the entire population. 'They are gentle, timid, careless, and almost passionless.' They differ in several respects from many eastern nations. Lying, though frequently resorted to as a protection against injustice and oppression, is not a national characteristic. The Siamese are inclined to be idle, inconstant, and exacting; but they are sincere, very affectionate in their domestic relations, witty in conversation, and, like the Chinese, expert in mimicry. About a third of the whole population are Chinese, who are great emigrants, but who, wherever they go, preserve their own language, customs, costume, habits, and social organisation. There are, it is estimated, 1,500,000 Chinese in S.; in Bangkok alone there are 200,000. All the active business of the country is in their hands. The Laos people (see SHAN STATES) are also very numerous in the country, and there are considerable numbers of Malays and Cambodians. The religion of the Siamese is Buddhism (q. v.), which inculcates the

highest veneration for life in whatever form. A Siamese will not kill vermin or serpents; and the tameness of many creatures that in Europe flee from the presence of man, is observed by all strangers. The use of Betel (q. v.) is almost universal in Siam. All the *belles* of S. stain their teeth black. The Siamese are extremely ceremonious in their intercourse one with another. An inferior crouches and crawls on the ground before a dignitary, and speaks of himself as 'your slave—a hair—a little beast.' They are a small well-proportioned race, with olive-coloured skin, and black hair, of which all that they allow to grow is a tuft about two inches long on the top of the head—the rest being shaven off. They are remarkably fond of jewellery and ornaments, and the dresses of the higher functionaries and nobles is splendid and beautiful. They are fond of music; have a number of good native instruments, as well as the common European ones, and are skilful performers.

The government is an absolute and hereditary monarchy, and there are two kings. The First King is the actual monarch; the Second King, who receives about one-third of the revenue, and has an army of 2000 men, seems to occupy the place of first counsellor, and is invariably consulted by the First King before any decisive step in the administration of affairs is taken. Both the present monarchs can speak and write English, have been careful and appreciative students of the great English writers, understand the use of the sextant and chronometer, and are well versed and deeply interested in the mechanical arts. The kings are assisted in the administration by a cabinet and council.

History.—The annals of the Siamese begin about five centuries B. C. But nothing authentic is known of the history of the country till 1350, in which year Ayuthia, the former capital, was founded. Cambodia was first conquered in 1532, and in this century the Siamese dominion extended to Singapore. The present dynasty ascended the throne in 1782. There have been numbers of Protestant and Catholic missionaries in S. since the year 1828, but so far as the Siamese are concerned, their labours have been almost if not altogether fruitless.—For further information on this most interesting country and people, see Bowring's *Siam* (Lond. 1857).

SIAM, GULF OF, an important arm of the Chinese Sea, is bounded on the N. and W. by Siam, on the S.-W. by the Malay peninsula, and on the N.-E. by Cambodia. At its entrance between Cambodia Point and the peninsula of Patani on the Malay Peninsula, it is 235 miles wide, and from the line drawn between these two points it extends inland in a north-west direction to the mouth of the Meinam, a distance of 450 miles. Four great rivers, navigable to a considerable distance from their mouths, and the chief of which is the Meinam (see SIAM), fall into the gulf. It is unvisited by hurricanes of any kind, and shipwrecks here are very rare.

SI'AMESE TWINS, a name given to two youths, Eng and Chang, born of Chinese parents in Siam, in 1811, having their bodies united by a band of flesh, stretching from the end of one breast-bone to the same place in the opposite twin. The survival to advanced life of such a *lusus naturæ* makes this one of the most remarkable cases on record. A union of the bodies of twins by various parts is not an unusual occurrence (see MONSTROSITY). Ambrose Paré has depicted instances of union by the back, belly, and forehead. The last occurred in two girls, who lived to the age of ten years, when one of them dying, a separation was made: the wound of the living girl assumed a bad character, and soon proved fatal. The Hungarian sisters, who lived about a century since, were united by the back, had one passage from the intestines, and each had one from the urinary organs. They died when they were 22 years of age. The Siamese twins were purchased of their mother at Meklong, a city of Siam (q. v.), and were brought to America by Captain Coffin and Mr Hunter in 1829. On examination, the connecting band seemed to have united them at first face to face, but constant traction had so changed its direction, that they stood partially side by side. Its length above was about two inches; below, nearly four; from above, downwards, it measured three inches; and its greatest thickness was one and a half inch. It is covered with skin, and when the centre is touched, both feel it; but on touching either side of the median line, only the nearest individual is sensible of it. The connection between the Siamese twins presents many interesting points in regard to physiology and pathology, for although they form two perfectly distinct beings, they appear most frequently to think, act, and move as one individual.

After realising a competence by the exhibition of themselves in the various countries of Europe and America, the Siamese twins settled in North Carolina, where they were married to two sisters, and had offspring. Owing to domestic quarrels, however, two houses were found necessary, each living with his wife a week at a time alternately. Ruined by the late disastrous war, the Siamese twins again exhibited themselves to the public, to repair their shattered fortunes.

For a full account of the structural peculiarities of such cases, see St. Hilaire's *Histoire des Anomalies de l'Organisation d'Homme et des Animaux.*

SIARA, properly, CEARA (q. v).

SIBBALD, SIR ROBERT, an eminent Scottish naturalist, born at Edinburgh, 15th April 1641, of a good family (the Sibbalds of Balgonie, in Fife), studied at the High School and university of Edinburgh, and afterwards pursued his medical studies at Leyden, Paris, and Angiers; settled as a physician in Edinburgh in 1662, devoted much time to botany and zoology, and aided Sir Andrew Balfour in establishing a botanic garden in Edinburgh. Having inherited an estate, he retired from medical practice, but continued his scientific pursuits; was appointed by Charles II. his Majesty's Geographer for Scotland, and was encouraged to prepare a work on the geography and natural history of his native country. His death is supposed to have taken place in 1722. He published many pamphlets on medical subjects, natural history, Scottish history, antiquities, &c. The work for which he is now chiefly remembered is his *Scotia Illustrata, sive Prodromus Historiæ Naturalis*, &c. (fol. Edin. 1684), a work of great merit for its time, but his *Collection of Several Treatises in Folio Concerning Scotland, as It was of Old, and also in Later Times* (Edin. 1739), is not without value.

SIBE'RIA, a vast territory in Northern Asia, belonging to Russia, and including all the Russian possessions in that continent, with the exception of the Transcaucasian and Armenian provinces, is bounded on the N. by the Arctic Ocean; on the E. by the seas of Kamtchatka, Okhotsk, and Japan, all of them arms of the Pacific Ocean; on the W. by the Ural Mountains, Ural River, and Caspian Sea. On the S., its boundary is constantly tending southwards, and according to the latest authorities, consists at present of a line running in lat. 45° N., between the Caspian and Aral Seas, crossing the latter to a point on the eastern shore in lat. 43° 40′ N., thence (enclosing the eastern seaboard of the

Aral Sea. Its boundary thence eastward is undefined, since Samarkand, capital of Bokhara, in lat. 40°, was annexed in 1868, and the N. borders of Afghanistan will shortly be, if they are not already, the S. boundary of Russia, thence N.E. by the Thian Shan Mountains to the meridian of 80°, and N. and N.E. to the Altai Mountains, in lat. 49°, thence N.N.E. to lat. 55° N., long. 96° E., S.E. to Kiachta (q. v.), eastward to the Argun River, which it follows to the Amur, and the latter to long. 135° E., when it trends in a S.S.E. direction, ascending the Usuri tributary for 200 miles, and then running straight S.W. to the sea in lat. 42° 30′ N., and long. 130° 30′ E. S. is divided for administrative purposes into the following 4 governments and 7 provinces:

	Surface in Eng. sq. m.	Pop. (1863).
Governments—		
Tobolsk,	565,920	1,105,647
Tomsk,	329,783	716,576
Jeniseisk,	958,042	323,014

Ural, Turgai, Akmolnsk, Semipalatinsk,	780,765	1,300,000
Total,*	5,758,840	4,988,644

or about five inhabitants to every 5¾ English sq. miles. The northern and eastern shores are very irregular in form, jutting out frequently into bold peninsulas and promontories, and being indented with numerous immense inlets, chief of which are the estuaries of the Obi (575 miles in length) and of the Yenesei; the Gulf of Anadir, and the sea of Okhotsk. All the island groups to the north of S., and the Aleutian Isles, some of the Kurile Isles, and Sakhalin or Saghalien on the east coast, are considered to belong to Siberia. The Liakhoff group, near the mouth of the Lena, consists of three islands, from 60 to 100 miles long by 20 to 40 broad, and of numberless islets: they are completely barren, and present in their soil and subsoil alternate layers of sand and ice, in which are embedded the fossil remains of numerous animals. The greatest length of S. is 5600 miles from north-east to south-west, and the greatest breadth 2170 miles from north to south. A country of such vast extent (one-half larger than Europe) must necessarily exhibit great varieties of climate; and we accordingly find in the northern regions, much of which lies far within the Arctic Circle (Cape Sievero Vostochnii, the most northerly promontory of S., and of the Old World, being in lat. 78° 25′ N.), an extensive tract bordering on the ocean, composed of swamp, moorland, and mossy flats, covered with snow and ice for one half of the year, and even during the greatest heats of summer, released from its icy bonds only to the depth of a few inches below the surface of the soil. The ocean, its northern boundary, is frozen for miles seaward during more than half the year, and during the remaining months, the numberless icebergs and floes which crowd the sea, and continually come into collision, render the navigation so dangerous that no complete hydrographic survey of the coast has yet been made. On the southern boundary of this semi-barren zone, stunted misshapen bushes and trees are found; and as we advance southwards, vegetation appears in the form of extensive forests of birch, fir, and larch, which clothe the plains and hill-sides, and are interspersed with stretches of pasture of moderate quality. After crossing the parallel of lat. 64° N. in West S., and that of lat. 61° N. in East S., the more hardy cereals, barley, oats, and rye, begin to appear, and the soil increases in fertility, sometimes to an extraordinary extent, thick woods of Siberian cedar and other trees clothe the mountain sides, and the valleys, especially along the banks of rivers, are in a state of continuous cultivation. The fertility of great portion of the governments of Tobolsk and Tomsk, especially of the *Baraba* and *Ishim* steppes, is proverbial, and they are the great granaries of Russia and Northern Europe. The whole of Western S. is one great plain, sloping from its southern boundary, where the average elevation is 2000 feet, northwards to the Arctic Ocean; with the exception of the small corner in the south-west, which is drained into the Caspian and Aral Seas. Eastern S. is more hilly and less fertile than the western portion, but the valleys and hill-sides afford good pasture, though agriculture, from the nature of the country, is little prosecuted. Four-fifths of S. is drained by the three immense rivers, Obi (q. v.), Yenesei (q. v.), and Lena (q. v.), which traverse the country throughout its whole breadth, and by a number of smaller rivers, all of which flow to the Arctic Ocean; the remainder either belongs to the Caspian and Ural basin, the various lake basins, or is drained by the Amur and other rivers which empty themselves into the Pacific. S. has a large number of lakes, some of which are little else than salt marshes; the largest of them are Lake Baikal (q. v.), Lake Balkash (q. v.), Lake Tchany, Lake Dzaisang, or Saisang, and Lake Issyk-kul. The chief mountain-range of S. is the Altai chain, which forms the southern boundary towards Mongolia, and ramifies eastwards and northwards from the region of Lake Baikal, covering a large portion of the surface of Eastern Siberia. The Stanovoi range stretches from the Amur north-east through Okhotsk; and there are a few ranges of small height in the centre of Siberia. The Yablonnoi Mountains, which have long found a place in books of geography, were shewn by the Russian exploring commission (1863) to have no existence, the place where they were supposed to be situated being an undulating plateau. Among the wild animals of S. are the reindeer in the northern flats, and on the high mountains of the south; the arctic or black fox, and white bear in the north; the sable, ermine, marmot, marten, squirrel, Caspian antelope, and wild sheep—all in the south; and the lynx, wolf, wild-boar, and glutton are generally diffused. Camels are found among the Kirghiz, along with the broad-tailed sheep, the Russian sheep being also domesticated in S.; and horses of good quality, an inferior sort of cattle of the Russian breed, and a large wolfish looking dog, used chiefly to draw sledges, complete the list of domestic animals. Fresh and salt water fish abound, and feathered game is plentiful in the south. The mineral wealth of S. is great: gold, silver, copper, and lead are found in all the mountainous districts on the west and south; platinum, iron, and precious stones, including diamonds, are found on the eastern slopes of the Ural; zinc, antimony, arsenic, plumbago, and valuable emerald and topaz mines are worked in the districts north of the Amur; and porphyry, malachite, jasper, and salt (from the steppes) are common. More than half of the inhabitants of the central and western provinces are Russians and Poles, or of Russian and Polish descent, and these have been sent to the country either as exiles, on account of political or criminal offences, or as

* The recent acquisitions in Bokhara have enlarged the area of Russia in Central Asia, but to what extent possession has actually reached is not at present (Oct., 1871) ascertained. Portions of Eastern Turkestan will probably be annexed at an early date.

government colonists. The most abandoned class of exiles are kept to hard labour in the mines; others are put to less laborious, but still compulsory work; and a third portion are settled in specified districts, under surveillance of the police, and allowed to employ themselves as they choose. This last class chiefly employs itself in trapping those animals whose skins and furs form valuable articles of trade. In the north-west are found the Samoieds, and adjoining them the Ostiaks, both of whom live by hunting and fishing alone. In the south are the nomad tribes of the Kirghiz (q. v.) and Kalmucks (q. v.), both cattle-breeding peoples, though the latter have now partially adopted a settled mode of life, and manufacture iron and gunpowder. Next to them, on the borders of Manchuria, are the Buriats, a people of Mongol origin, and the most numerous tribe in S.; to the north of whom are the Yakuts and Tunguses, of Tartar origin, who are spread over the whole of Eastern S., from the town of Irkutsk to the Stanovoi range; and live mostly by hunting. The Tchuktchis, an Esquimaux race, and the Koriaks inhabit the north-east corner, and the Manchus are the population of the Amur territory. Manufactures are unimportant, and are confined to the principal towns; the barter trade in European goods is carried on at Obdorsk, Ostrovnoe, Yakutsk, and Petropavlovsk; and the transit-trade with China through Kiachta (q. v.), the imports from China being tea of the finest quality, sugar, silk, cotton, wool, grain, fruits, &c.; and the exports to that country, cotton and woollen cloths, linen, furs and skins, leather, and articles of gold and silver. The exports to Russia are the natural produce of the country, and are transported westward to the frontier by alternate land and river carriage, to Tobolsk, thence over the Ural Mountains to Perm. Reindeer sledges are the usual means of transport in winter. Fairs are held at stated periods in certain localities, and much of the trade of the country is there transacted. S. seems to have been first made known to the Russians by a merchant named Anika Stroganoff; and soon after, the conquest of Western S. was effected by the Cossack Vassili Yermak, an absconded criminal, at the head of a numerous band of wild followers. After Yermak's death in 1584, the Russians pursued their conquests eastward, founding Tomsk in 1604, and though they often experienced serious reverses, their progress was rapid, the Sea of Okhotsk being reached in 1639, and Irkutsk founded in 1661. Frequent disturbances have occurred between the Russians and the Chinese and Tartars, which have resulted in the extension southward of the Siberian boundary into Manchuria and Turkestan, but that to the north of Mongolia remains much as it was originally. Eastern S. was little known till recently, and several explorations made under the auspices of the Russian government have done much to increase our knowledge of that still comparatively unknown territory. In 1863, a service of steam-packets was established between Irbit, in Perm, and the towns on the Obi and its tributaries; and more recently, a line of telegraph has been constructed between Moscow and Irkutsk, which it was intended to continue to Behring's Strait and San Francisco, but the project has been abandoned.—See Atkinson's *Oriental and Western Siberia* (London, 1858); and Pumpelly's *Across America and Asia* (New York, 1870).

SI'BYL (Gr. *Sibulla*, according to the old derivation from *Dios Boule;* Doric, *Sios Bolla*—the 'Will or Counsel of God'), the name anciently given to several prophetic women, whose history, in so far as they have any, has come down to us in a wholly mythical form, if, indeed, such beings ever existed at all! Their number is differently given; some writers (Ælian, for example) mention only four—the Erythræan, the Samian, the Egyptian, and the Sardian; but in general ten are reckoned, viz., the Babylonian, the Libyan, the Delphian, the Cimmerian, the Erythræan, the Samian, the Cumæan, the Trojan or Hellespontian, the Phrygian, and the Tiburtine. Of these, by far the most celebrated is the Cumæan, identified by Aristotle with the Erythræan, and personally known by the names of Herophile, Demo, Phemonoë, Deiphobe, Demophile, and Amalthæa. She figures prominently in the 6th book of Virgil's *Æneid*, as the conductor of the poet into the realm of the shades. The Roman legend concerning her (as recorded by Livy) is, that she came from the east, and appearing before King Tarquin the Proud, offered him nine books for sale. The price demanded appeared to the monarch exorbitant, and he refused to purchase them. She then went away, destroyed three, and returning, asked as much for the remaining six as for the nine. This was again refused, whereupon she destroyed other three, and once more offered to sell him the rest, but without any abatement of the original price. Tarquin was struck by her pertinacity, and bought the books, which were found to contain advices regarding the religion and policy of the Romans. They were preserved in a subterranean chamber of the temple of Jupiter on the Capitoline, and were originally intrusted to two officials (*duumviri sacrorum*), appointed by the senate, who alone had the right to inspect them. The number of keepers was afterwards increased to 10 (*decemviri*), and finally, by Sulla, to 15 (*quindecemviri*). In the year 84 B. C., the temple of Jupiter having been consumed by fire, the original Sibylline books or leaves were destroyed, whereupon a special embassy was despatched by the senate to all the cities of Greece, Italy, and Asia Minor, to collect such as were current in these regions. This being done, the new collection was deposited in the temple of Jupiter after it had been rebuilt. Spurious Sibylline prophecies—or what were regarded as such—accumulated greatly in private hands towards the close of the Republic; and Augustus, fearing, perhaps, that they might be turned to political uses, ordered them all to be given up to the city-prætor, and burned them. More than 2000 were destroyed on this occasion. The remainder were kept in the temple of Apollo, on the Palatine, under lock and key; but the whole perished during the burning of Rome in the time of Nero. Other collections were made; and as late as the 6th c., when the city was besieged by the Goths, there were not wanting some who pretended to predict the issue from a consultation of these venerable oracles. It is, however, beyond doubt, that as early, at least, as the 2d c. A. D., when enthusiastic men sprung up in the Christian church, prophesying in a poetic-oracular style (whence they were sometimes called *Sibyllists*), the Sibylline books were much interpolated and falsified to assist the progress of the new faith. The utterances of these Christian Sibyllists form a special department of early ecclesiastical literature, and are a mixture of Jewish, Pagan, and Christian ingredients. The collections of them also bear the name of 'Sibylline Books.' An edition was published by Gallæus, at Amsterdam, in 1689, and was entitled *Oracula Sibyllina;* fragments have also been edited by Angelo Mai (Milan, 1817) and Struve (Königsberg, 1818).—Consult Bleek, *Ueber die Entstehung und Zusammensetzung der uns in acht Büchern erhaltenen Sammlung Sibyllinischer Orakel* (in Schleiermacher's *Theologische Zeitschrift*, Berl. 1819), and Thorlacius, *Libri Sibyllistarum Veteris Ecclesiæ* (in his *Prolusiones et Opuscula Academica*, vols. 4 and 5, Copenh. 1821—1822).

SICI'LIAN VESPERS, the name given to the massacre of the French in Sicily, on the day after Easter (March 30), 1282, the signal for the commencement of which was to be the first stroke of the vesper-bell. In the articles NAPLES, KONRADIN, MANFRED, &c., it is related how Charles of Anjou, the brother of Louis IX. of France, had deprived the Hohenstaufen dynasty of Naples and Sicily, and parcelled out these kingdoms into domains for his French followers; but his cruelty towards the adherents of the dispossessed race, his tyranny, oppressive taxation, and the brutality of his followers, excited among the vindictive Sicilians the deadliest animosity. The aged Giovanni da Procida, a steady partisan of the Hohenstaufen family, took the lead in directing and systematising a conspiracy against Charles and his followers; and after a visit to Pedro of Aragon (the husband of Constance the cousin of Konradin, and the next heir to Naples and Sicily), whom he found willing to undertake the conquest of Sicily, he returned to his self-imposed duty in the island. On the evening of Easter-Monday, the inhabitants of Palermo, enraged (according to the common story) at a gross outrage which was perpetrated by a French soldier on a young Sicilian bride, precipitated the accomplishment of the scheme by suddenly rising upon their oppressors, putting to the sword every man, woman, and child of them, not sparing even those Italians and Sicilians who had married Frenchmen. This example was followed, after a brief interval, by Messina and the other towns, and the massacre soon became general over the island: the French were hunted like wild beasts, and dragged even from the churches, where they vainly thought themselves secure. More than 8000 of them were slain by the Palermitans alone. Only one instance of mercy shewn to a Frenchman is on record, the fortunate subject being a Provençal gentleman, Guillaume des Porcellets, who was much esteemed for his probity and virtue. The governor of Messina also succeeded in passing the strait with his garrison before it was too late.—See Amari, *La Guerra del Vespro Siciliano* (Palermo, 1841; reprinted at Paris, 1843), and Possien and Chantrel's *Les Vêpres Siciliennes* (Paris, 1843).

SICILIA'NA, in Music, a name given to a slow, soothing, pastoral description of air, in $\frac{6}{8}$ time; so called because the dance peculiar to the peasantry of Sicily possesses this character.

SI'CILY, the largest, most fertile, and most populous island in the Mediterranean Sea, lies between lat. 36° 38′—38° 18′ N., and between long. 12° 25′—15° 40′ E., and is separated from the mainland of Italy by the Strait of Messina. Its shape roughly resembles a triangle (whence the early Greek navigators gave it the name of *Trinacria*, the 'Three-cornered')—the eastern coast, from Capo del Faro in the north to Capo Passaro in the south, forming the base; and the northern and south-western coasts the sides, which gradually approach each other towards the north-west. The length of the base is 145 miles; of the northern side, 215 miles; and of the south-western, 190 miles: the circumference of the island, including the sinuosities of the coast, is estimated at 624 miles. Area about 10,000 sq. miles. Pop. according to the census of 1862, 2,391,802. Capo Passaro, at the south-eastern extremity, is only 56 miles from Malta; and Capo Boco, near Marsala, at the north-western, only 80 miles from Cape Bon on the African coast.

Physical Geography.—The island of S., like the mainland of Italy, is traversed throughout its entire length by a chain of mountains, which may be looked upon as a continuation of the Apennines (q. v.). This chain, beginning at Capo del Faro on the Strait of Messina, runs in a south-south-western direction as far as Taormina, where it turns off to the west, and stretches across the whole island, keeping, however, much nearer to the northern than to the south-western coast. The first part of the chain, from Capo del Faro to Taormina, is called the Peloric range (anc. *Neptunius Mons*), which in Monte Dinnamare attains the height of 3260 feet; the second and much the longer part is called the Madonian range (anc. *Nebrodes Montes*), which, in the Pizzo di Palermo, rises to an elevation of 6328 feet. It forms the great watershed of the island. Towards the north-western coast, the chain breaks up into irregular and often detached masses, such as Monte Pellegrino (1963 feet) and Monte San Giuliano (2184 feet). About the centre of the chain, a range branches off through the heart of the island to the south-east; at first wild and rugged, but afterwards smoothing down into table-lands, which in turn slope away tamely to the sea. There are innumerable other spurs to the south from the great Madonian chain, of inferior length and elevation, but none of these require special mention. The volcano of Etna, which rises in solitary grandeur on the eastern coast, is separately described. See ETNA. S. is not, on the whole, a well-wooded country, but forests of considerable size are found here and there—as, for example, the royal forests near Caronia and Mezzojuso, the forest-zone of Etna, &c.—In the interior of the island there is not much level land, but on several parts of the coast there are extensive plains, generally of great fertility. The principal of these are the great plain of Catania (anc. *Campi Leontini*), out of which rises Etna; the plains of Palermo, termed the *Conca d'Oro*, or 'Golden Shell,' of Castellamare, of Licata, and Terranova.—Although rivers are numerous, none are navigable. The largest are the Simeto or Giarretta, the Cantara, the Salso, the Platani, and the Belici.

Climate.—The climate of S. is very warm, but salubrious, except in low-lying places, where there is a mephitic atmosphere. The best health is enjoyed in the lower region of Etna, which is very densely peopled, although exposed to eruptions and violent earthquakes. The heat is intense in summer when the sirocco blows. After the autumnal equinox, violent winds are prevalent, torrents of rain fall, and all along the coasts the atmosphere is charged with moisture and fogs. The earthquakes begin about the end of winter, and do great damage. Snow and ice are rarely to be seen except on Etna.

Geology and Mineralogy.—The primary rocks in the mountainous districts are chiefly quartz, granite, and mica. In some parts, these are overlaid by limestone rocks. Most of the lower ranges of hills are of calcareous formation, and are rich in metallic ores. Sulphur forms the chief mineral wealth of Sicily. Immense beds of it are found in the central and northern parts of the island. The English imported 57,000 tons of it in 1867, and the mines are worked by Cornish miners and their descendants.

Soil, Agriculture, &c.—The soil of the island is so fertile that very little labour is required to raise the crops. In many valleys there is rich soil to the depth even of 40 feet. In Catania, decomposed lava is spread over the ground, greatly increasing its fertility. The crops of grain are large, and might be prodigious if agriculture were better understood; the harvests are such that they recall to mind the words of Livy, in speaking of S.: 'Populoque Romano, pace ac bello, fidissimum annonæ subsidium' (lib. xxvii. 5). In the most ancient times, agriculture was sedulously prosecuted, but it began

to decline when the island was deprived of its independence by the Carthaginians. In more recent times, the restrictions on the exportation of grain served not only to keep agriculture from making any progress, but also to put a drag upon the commerce of the country, which, on every attempt made to raise itself, was met by fresh obstacles in the shape of new taxes. The Italian government has greatly alleviated the obstacles to agriculture, and the salutary effects of the change of system are already apparent. The soil produces corn, maize, flax, hemp; excellent cotton near Mazzara and in Catania; sugar, equal to that of the East Indies, along the southern coast; grapes (350,000 acres), olives (125,000 acres, with an annual yield in oil of 15,000 tuns), saffron, oranges, lemons, citrons, pomegranates, figs, pistachios, dates, castor-oil, mulberry, sumach, tobacco, and manna. The vine has been cultivated with the greatest care at Marsala since 1789, when an English firm settled there began to export it. Now, upwards of 5,000,000 gallons are annually exported to England, America, and India.—S. possesses the best tunny-fisheries in the Mediterranean. The fisheries for coral at different places on the coast are also industriously carried on, and on an average, about 2100 lbs. are annually obtained.

Manufactures, Commerce, &c.—The manufactures of S. are insignificant. Such manufacturing industry as exists is nearly altogether confined to the preparation of silk, cotton, and leather.—The most important articles of export are sulphur, sumach, fruits, and wine; of import, cottons, woollens, silks, linens, earthenware, hardware. Great Britain, France, and the United States are the countries with which the Sicilians chiefly carry on commerce. The total value of the exports in 1862 amounted to £2,830,057; of the imports, to £3,254,903.

Religion, Education, &c.—With the exception of about 58,000 Greeks, and a few thousand Jews, the inhabitants are all Roman Catholics; but though equally ignorant, they are not so superstitious as the Neapolitans; at least their superstition has not destroyed their love of political freedom, as has repeatedly been evinced in their history—most recently in the ardour with which they responded to the summons of Garibaldi to liberate themselves from the tyranny of the Bourbons. There are three universities—at Palermo, Catania, and Messina; and also a Collegio de' Nobilé at Palermo.

Political Divisions.—S. is divided into 7 provinces or prefectures—viz., Palermo, Messina, Catania, Noto or Siracusa, Caltanisetta, Girgenti, and Trapani. Each province is subdivided into 3 or 4 districts, and these again into numerous *communi*, or 'townships.' Over the province is placed an *intendente*, or, as he is now called, a 'prefect;' over the district, a sub-prefect; and over the commune, a *sindaco* ('syndic,' or 'mayor'). The prefect presides over every department of the provincial administration, and also over the provincial council—a body composed of from 15 to 20 landholders, who meet once a year, and sit for 20 days, examining the accounts of the province, and framing the provincial budget. The two subordinate divisions have also their 'councils;' and the members of all three are appointed either by the king or by the prefect. Of course, this insular self-government does not supersede the necessity of sending Sicilian deputies to the national parliament.

History.—S. was inhabited, in pre-historic times, by a people who bore the name of *Siculi* or *Sicani*, and who—according to a universally received tradition—crossed over into the island from the southern extremity of the mainland. Their names and every fact that we can ascertain about them, lead to the supposition that they were members of the great Latino-Italian family that, entering Italy from the north, gradually pushed its way across the Apennines to the peninsula of Bruttium (see article Rome). Beyond this rational conjecture, however, we cannot proceed, and the actual history of S. only begins to emerge out of utter darkness with the establishment of Greek and Phœnician colonies. The earliest Greek colony, that of Naxos, was founded 735 B. C.; the latest, that of Agrigentum, 580 B. C. During the intervening century and a half, numerous important colonies were established (either directly from Greece or as offshoots from the older Greek settlements in the island); Syracuse (734 B. C.), Leontini and Catana (730 B. C.), Megara Hyblæa (728 B. C.), Gela (690 B. C.), Zancle, later Messana (date of origin uncertain), Acræ (664 B. C.), Himera (648 B. C.), Mylæ (date of origin uncertain), Casmenæ (644 B. C.), Selinus (628 B. C.), Camarina (599 B. C.), Agrigentum (580 B. C.). The earlier history of these cities is almost unknown. What is recorded is vague and general. We read that they attained great commercial prosperity, that they subjugated or wrested from the Siculi, Elymi, and other 'native' tribes, large portions of neighbouring territory; and that their governments (like those of the republics in the mother-country) were at first oligarchical, and latterly democracies or 'tyrannies;' but it is not till the period of the 'despots' that we have detailed accounts. Then the cities of Agrigentum and Gela acquire prominence—the former, under the rule of Phalaris (q. v.), becoming, for a short time, probably the most powerful state in Sicily; and the latter, under a succession of able tyrants, Cleander, Hippocrates, and Gelon (q. v.), forcing into subjection most of the other Greek cities. Gelon, however, transferred his government to Syracuse (one of his conquests), which now became the principal Greek city of Sicily—a dignity it ever after retained. Contemporary with Gelon, and possessed of the same high capacity for governing, were Theron, 'tyrant' of Agrigentum, and Anaxilaus, tyrant of Rhegium, and conqueror of Zancle, to which he gave the name of Messana. Meanwhile, the Carthaginians—a people wholly different from the Greeks in language, religion, origin, and civilisation—had obtained possession of the Phœnician settlements in Sicily. The first appearance of the Carthaginians in the island dates from 536 B. C.; but the steady growth of the Greek cities in wealth and power, long confined their rivals to the north-western part, where their principal colonies were Panormus, Motya, and Soloeis. The first open trial of strength took place in the great battle of Himera, where the Carthaginian army was utterly routed by Gelon, and its leader, Hamilcar, slain. The Gelonian dynasty at Syracuse fell 466 B. C., after experiencing various fortunes. During the next fifty years, the island had peace. In 410 B. C., however, the war between the Carthaginians and Greeks for the possession of the island was renewed. The successes of the former were great and permanent. Selinus, Himera, Agrigentum, Gela, and Camarina, fell into their hands in less than five years; and it was not till Syracuse had got a new 'tyrant,' the famous Dionysius (q. v.) the Elder, that fortune again began to smile on the Greeks. Even he, however, could not wrest from the Carthaginians what they had already won; and after the war of 383 B. C., a peace was concluded, which left Dionysius in possession of the eastern, and the Carthaginians of the western, half of the island. The dissensions and tumults that followed the decease of Dionysius, illustrate forcibly the peculiar dangers to which the Greek republics, either at home or abroad, were prone; but we can

only afford to notice the triumph of the popular party under Timoleon (343 B. C.), and the splendid victory of the latter over the Carthaginian generals, Hasdrubal and Hamilcar, at the river Crimisus, 340 B. C. Once more Greek influence was in the ascendant, but the rule of the bold and ambitious tyrant Agathocles (317—289 B. C.) proved in the main disastrous to Greek supremacy. After his death, Syracuse lost her hold over many of the Greek cities, which established a weak and perilous independence, that only rendered the preponderance of the Carthaginians more certain. Finally, Pyrrhus (q. v.), king of Epirus, was invited over to help his countrymen, and in 278 B. C. he landed in the island. The brilliant adventurer—one of the most romantic figures in classic history—for a time swept everything before him. Panormus, Ercte, and Eryx were captured; and though he failed to make himself master of Lilybæum, he might probably have forced the Carthaginians to surrender it, had he not been thwarted in his designs by the miserable discords and jealousies of the people whom he came to save. As it was, Pyrrhus left Sicily in about two years; and in all likelihood the island would have sunk into a Carthaginian possession, had not a new power appeared on the stage—viz., the Roman. The struggle for supremacy between Rome and Carthage—the most tremendous struggle in ancient history—is sketched in the article ROME, and in the biographies of the leading generals, and therefore need not be narrated here. Suffice it to say, that in 246 B. C., Carthaginian S., and in 210 B. C., the whole island, became a Roman 'province'—the first Rome ever held. Henceforth it shared the fortunes of the great state to which it was annexed, and its special history need only be rapidly glanced at. In 135—132 B. C., and again in 103—100 B. C., it was the scene of two formidable slave-insurrections, during which it was frightfully devastated. Its fertility, and the wealth of its citizens and landholders, were also powerful temptations to greedy and unscrupulous governors, of whom we have a specimen in Verres (prætor 73—70 B. C.), 'damned to everlasting fame' in the Orations of Cicero. Augustus visited S. after the close of the civil wars, and established some colonies; but it does not seem to have prospered under the empire; and in 440 A. D. it was conquered by the Vandals under Genseric. The Vandals, in their turn, were compelled to cede it (480 A. D.) to Theodoric, king of the Ostrogoths, in whose hands it remained till 535 A. D., when Belisarius conquered and annexed it to the Byzantine empire. In this condition it remained till 827, when the Saracens invaded the island, and after a protracted struggle, lasting for 114 years, expelled the Byzantine Greeks, and made themselves masters of Sicily. They kept possession of it for upwards of a century, but after a contest of 30 years, were driven out by Robert Guiscard (q. v.) and Roger de Hauteville (q. v.), at the head of a body of Normans, aided by the 'native' inhabitants, whom we conjecture to have been much the same as they were in the old classic times—for the successive waves of barbaric and Saracenic invasion that swept over the island, appear to have left little trace of their action. Even to this day, it is highly probable that the people of S. are largely the descendants of the early Siculi. The Normans held rule in the island from 1072 to 1194; and the Norman 'Kingdom of Sicily and Naples,' or 'Kingdom of the Two Sicilies,' dates from 1130, when Roger II. obtaining possession of most of the continental dominions of his uncle, Robert Guiscard, assumed the title of king. During the rule of the Swabian dynasty (see HOHENSTAUFEN, HOUSE OF), 1194—1258, the political history of S. is the same as that of Naples; but in 1282, after the dreadful massacre of the French, known as the Sicilian Vespers (q. v.), it again became independent, chose for its king Pedro III. of Aragon, who was the sole representative by marriage of the House of Hohenstaufen, and remained in the possession of the Aragonese sovereigns till 1505, when the union of the crowns of Castile and Aragon—in other words, the rise of the Spanish monarchy in the persons of Ferdinand and Isabella, placed it under the dominion of Spain. The fortune of war also gave Ferdinand the possession of Naples; and the Spanish kings retained both countries (which they governed by viceroys), until the *War of the Spanish Succession* (q. v.) (1700—1713). By the treaty of Utrecht (1713), S. was separated from Naples; and handed over to Victor Amadeus, Duke of Savoy, who, however, restored it to the crown of Naples by the treaty of Paris, seven years after, receiving in exchange the island of Sardinia. From 1720, the two countries continued under the same dynasty, the House of Austria, 1720—1734; and the Spanish Bourbons, 1734—1860 (if we except the brief rule of the French in Naples, 1806—1815, when Joseph Bonaparte, and afterwards Joachim Murat, were kings), down to the period of Garibaldi's invasion (see ITALY, and GARIBALDI), which resulted in the annexation of both to the new kingdom of Italy under Victor Emmanuel.

SICULIA'NA, a city of Sicily, province of Girgenti, and 8 miles west-north-west of the city of that name. It stands on the sea, and has a small, badly-situated harbour. Pop. 5981.

SI'CYON, the principal city of a very small but exceedingly fertile state of ancient Greece, Sicyonia, situated in the north of the Peloponnesus, having the Corinthian Gulf for its northern boundary, with Achaia on the W., Phlius on the S., and Corinth on the E. The territory was level towards the sea, somewhat mountainous in the interior, and well watered by the two rivers Asopus and Helisson, between which, on a triangular plateau, was situated S., about two miles south of the Corinthian Gulf, and ten north-west of Corinth. Round the three sides of the plateau ran a wall, which, combined with the precipitous nature of the heights that surrounded it, rendered the position of S. one of great strength. It is supposed that at one time it had, like Athens, a double wall reaching from the city to the port on the Sea of Corinth. S. was anciently celebrated as a chief seat of painting and statuary (tradition asserting that the former was invented there), it having given its name to a school of painting which included among its disciples Pamphilus and Apelles, both natives of Sicyon. It was also the native city of Aratus (q. v.), the general of the Achæan League. There exist at the present day a few remains of the ancient city, as well as of the more modern buildings erected by the Roman conquerors of Greece, near which stands a small modern village named *Vasilika*.

SIDA, a genus of plants of the natural order *Malvaceæ*, containing a large number of species, annual and perennial herbaceous plants and shrubs, mostly natives of warm climates, and widely diffused. They generally abound in mucilage, and some of them are used in medicine in India, as the Mallow and Marsh-mallow are in Europe. They have also strong pliable fibres, which are employed for cordage and for textile purposes.—*S. tiliæfolia*, an annual, has long been cultivated in China, where it is called *King-Ma*, for the sake of its fibre, which is used like that of hemp. It is too tender for the climate of Britain, but its cultivation has been introduced into Italy and France.

SIDDONS, Mrs Sarah, was the daughter of Mr Roger Kemble, a provincial actor, and was born at Brecon, in South Wales, on July 5, 1755. As a mere child, she was brought on the stage on the occasion of a benefit of her father's; and from that time up to her 15th year, she continued to act as a regular member of his company. An attachment having sprung up between her and a young Mr Siddons, an actor, with the somewhat reluctant consent of her parents, she was married to him at Trinity Church, Coventry, on 26th November 1773, and in company with her husband, went to act at the Cheltenham theatre. Here she speedily drew great attention; and Garrick, hearing her praises in London, sent to Cheltenham a trusty emissary to report upon her. The result was an engagement offered her at the London Drury Lane Theatre, where, 29th December 1775, she made her first appearance, acting Portia in *The Merchant of Venice* to the Shylock of Mr Garrick. Her beauty and fine person pleased the audience, but as an actress she made no great impression, and at the close of the season she failed to secure a re-engagement. It was considered that this was to some extent due to her having vexed the irritable vanity of Garrick by an unintentional error in stage business, which made him act with his back to the public in one of his pet passages, a mortification which the great man was little enough to remember and resent.

Leaving London thus in failure in 1776, in 1782 she returned to it, to run a career of triumph as indisputably the greatest actress of her time. The intervening years she had passed in the exercise of her art on the stages successively of Birmingham, Manchester, York, and Bath, till the growth of her provincial reputation determined her recall to the metropolis. In 1784, her popularity was temporarily obscured by a calumny industriously circulated, which charged her with ungenerous and illiberal conduct towards certain of her fellow-performers; but with this trivial exception, till on the 29th June 1812, in her great character of Lady Macbeth, she took her leave of the public, her course was one long series of successes. Subsequently, she occasionally consented to reappear on the stage for charitable ends, or to promote a stage 'benefit,' in which she had a kindly interest. Her death took place in London, on the 8th June 1831.

As a tragic actress, Mrs. S. has probably never been equalled in Great Britain; as a woman, she was of unblemished reputation, and enjoyed the respect of all who knew her. She was the ornament of every society into which she went, and such was the estimation in which she was held, that she had access at will to almost any. Her genius is said to have been strictly a *stage* genius; elsewhere, she seems to have been a woman of no extraordinary parts. But she had a certain way of making her mediocrities imposing. She carried her tragedy manners with her to the drawing-room or the dinner-table: Scott has recorded the amusement with which at Abbotsford he heard her stately blank verse to the domestic:

'I asked for water, boy! you've brought me beer;'

and Sidney Smith used to say, it was never without a certain awe that he saw her '*stab the potatoes.*'

SIDE-BONES are enlargements situated above a horse's heels, resulting from the conversion into bone of the elastic lateral cartilages. They occur mostly in heavy draught horses with upright pasterns, causing much stiffness, but, unless when of rapid growth, little lameness. They are treated at first by cold applied continually, until heat and tenderness are removed, when blistering or firing must be resorted to.

SIDE'REAL CLOCK, a clock so regulated as to indicate *sidereal time*. See Day. The sidereal clock is a most important and to the practical astronomer, and is one of the indispensable instruments of an observatory.

SIDERO'GRAPHY (Gr. *sideros*, iron). The name applied by the inventor, Mr Dyer, to a process of printing with compound iron (or rather steel plates, for they are case-hardened after engraving) plates, instead of plain plates of copper or steel. It is the plan now usually employed in printing bank-notes in which more than one colour is given. The coloured parts of the design are cut out of the main plates, and movable pieces are exactly fitted in, so that they can be retracted or pushed forward at will. They are withdrawn whilst the main plate is receiving its ink, and they are pushed forward beyond whilst receiving their supply of ink. This being done, they are brought to one plane, and form a complete plate for printing from.

SIDERO'XYLON, a genus of trees of the natural order *Sapotaceæ*, having evergreen leaves and axillary clusters of flowers, natives of warm climates, and very widely distributed. They are remarkable for the hardness of their wood, which is sometimes called Iron-wood, and is at least in some species so heavy as to sink in water. The wood of *S. inerme*, called *Melkhout* at the Cape of Good Hope, is there much used for making boats, bridges, agricultural implements, &c.

SI'DI-BEL-A'BBÈS, a town of Algeria, in the province of Oran, and 50 miles south of the town of that name. It is fortified, and contains barracks, telegraph and post offices. Markets take place here every week. The soil in the vicinity is fertile; grain, tobacco, and fruit are the chief products. Pop. (1864) of commune, 6458.

SI'DLAW HILLS. See Forfarshire and Birnam.

SI'DMOUTH, a market-town and watering-place on the south coast of Devonshire, at the mouth of the little river Sid. S. was a borough and market-town, governed by a port-reeve, as early as the 13th century. It was anciently a place of some importance as a fishing-town and seaport, but the fishery has declined, and the harbour is in great measure filled up with sand and shingle, so that it is now accessible to small boats only. The town has for many years past been a favourite watering-place, remarkable for the mildness and salubrity of its climate. The hills on each side of the valley of the Sid rise to a considerable height, and, where they terminate on the sea-coast, form bold and lofty cliffs, east and west of the town, known respectively as Salcombe Hill and High Peak, about 500 feet above the sea. Owing to the narrowness of the valley, the town presents no large frontage towards the sea; but the esplanade, protected by a sea-wall, 1700 feet in length, built in 1838 to stop the encroachment of the sea, forms an excellent promenade. Villas and detached houses extend for some distance inland, up the valley of the Sid, on both sides of the stream. The town is neatly, though irregularly built, lighted with gas, and paved, and contains baths, public rooms, &c. Pop. (1861), parish, 3354; town, 2572. Some Roman remains have been found here. S. gives the title of viscount to the Addington family.

SIDNEY, Sir Philip, the son of Sir Henry Sidney, and Mary, sister to Robert Dudley, the favourite of Queen Elizabeth, was born at Penshurst, in Kent, on 29th November 1554. When ten years old, he was sent to school at Shrewsbury,

whence, in 1569, he went to Christchurch, Oxford. From Oxford, he passed to Cambridge, which he left with a high reputation for scholarship and general ability. In 1572, as the custom then was for young men of rank, he went abroad on his travels. He was in Paris when the Massacre of St Bartholomew took place, and narrowly escaped being one of its victims. Thereafter, he visited Belgium, Germany, Hungary, and Italy; and in 1575, he returned home, perfected in all manly accomplishments. His uncle, Dudley, Earl of Leicester, was at this time in the zenith of his fortunes, and for S. a court-career lay temptingly open. As a courtier, his success was great; and with Queen Elizabeth he became, and continued while he lived, a special favourite. In 1576, as a mark of her approval, he was sent on an embassy to the court of Vienna, from which he returned in the course of the year following. Shortly after, he had the boldness to address to the queen a 'Remonstrance' against her proposed marriage with Henry, Duke of Anjou, a union to which she seemed herself not indisposed. It is significant of the high favour in which he was held by her, that Elizabeth, imperious as she was in temper, and little inclined to brook such interference, seems scarcely at all to have in this instance resented it. About this time, a quarrel with the Earl of Oxford led to S.'s temporary retirement from court, during which, at Wilton, the seat of his brother-in-law, the Earl of Pembroke, he wrote his celebrated *Arcadia*. In 1583, he consoled himself for the marriage of Lady Penelope Devereux, to whom he had been ardently attached, and who figures as the Stella of his poems, by himself marrying Frances, the daughter of Sir Francis Walsingham. By this lady, he had one daughter, who survived him. In the spring of 1585, he is said to have meditated sailing with Sir Francis Drake in an expedition against the Spaniards in the West Indies, but to have been expressly forbidden by Elizabeth, on a ground of anxiety 'lest she should lose the jewel of her dominions.' It does not seem nicely consistent with this pretty story, that later in the same year she appointed him governor of Flushing, whither he went to take part in the war then being waged between her allies, the Hollanders, and the Spanish. As it proved, she thus sent him to his death. At the battle of Zutphen, in Gelderland, after behaving with conspicuous gallantry, and having a horse killed under him, he received a musket-shot in the thigh, and after lingering for some days in great suffering, he died at Arnheim on the 7th October 1586, in the 33d year of his age. A beautiful trait of humanity is recorded of him as he was being borne wounded from the field. He complained grievously of thirst, and a bottle of water was procured for him, from which, as he was about to drink, he was touched by the wistful look up at it of a mortally wounded soldier, who lay close by, and taking it untasted from his lips, he handed it to his fellow in need, with the words: 'Thy necessity is yet greater than mine.' The estimation in which S. was held by his countrymen was shewn in the passion of grief with which the news of his death was received. His body was brought to England, and after lying for some time in state, was buried with great solemnity in the old cathedral of St Paul's, a general mourning on the occasion being observed throughout the country. The universities issued three volumes of elegies on his death, and Spenser, in his *Astrophel*, mourned for the loss of one who as a friend had been dear to him.

The love and admiration which S. won from his contemporaries was mainly a tribute to the singular beauty of his character. His short life was illustrated by no brilliant achievement; and his literary genius, though true and exquisite in its kind, would scarcely of itself have sufficed to account for the fervour of regard he inspired. But the purity and nobility of his nature, and the winning courtesies in which its gentle magnanimity expressed itself, took captive all hearts whilst he lived, and have since kept sweet his memory. 'Sublimely mild, a spirit without spot,' he lives in the history of his country, as a rare and finished type of English character, in which the antique honour of chivalry is seen shading into the graces of the modern gentleman. His *Arcadia*, overrun as it is with the fantastic affectations of the time, may still be recognised by the reader who has patience to peruse it, as a work of indisputable genius, flushed with the lights of a fine imagination, and in its purity and tenderness of sentiment, giving an authentic reflex of the lovely moral nature of the writer. His other chief work, the *Defense of Poesie*, published in 1595, after all that has since been written in the way of philosophical exposition on this and cognate subjects, will even now be found to repay the attention of the reader. Many of his shorter poems, more especially some of his sonnets, are also of rare merit. See Fulke Greville's Biography of S., Zouch's Memoirs of S. (1808), and H. R. Fox Bourne's *Memoirs of Sir Philip Sidney* (1862).

SIDNEY, or SYDNEY, ALGERNON, grandnephew of the famous Sir Philip Sidney, was born in the year 1622. He received a careful education, and accompanied his father, the Earl of Leicester, to Denmark and France, whither the latter had been sent on embassies. In 1641, he served with some distinction against the rebels in Ireland, of which country his father was then Lord-lieutenant for the king. Subsequently, in 1643, along with his elder brother, the Viscount Lisle, he crossed to England, ostensibly to take service under the king, then at war with his parliament. The two brothers, however, on their arrival, joined the parliamentary forces. At the battle of Long Marston Moor, in which he was sharply wounded, Algernon's courage and capacity were conspicuous; and in evidence of the estimation in which he came to be held by his party, we find him, in 1646, Lieutenant-general of the Horse in Ireland, and governor of Dublin; and subsequently, in 1647, after receiving the thanks of the House of Commons for his services, appointed governor of Dover. The year before, he had been returned to parliament as member for Cardiff. In 1648, he was one of the judges at the king's trial, and though, for some reason not explained, he neither was present at the passing of sentence, nor signed the warrant of execution, his general approval of the proceedings is not doubted. He is reported to have afterwards spoken of the execution as 'the justest and bravest action that ever was done in England or anywhere else.' In principle a severe republican, he resented the usurpation of power by Cromwell, and during the Protectorate lived in retirement at the family seat of Penshurst, in Kent. In 1659, on the meeting of the restored parliament, S. was again in his place. He was nominated one of the Council of State, and shortly after despatched to Denmark on a political mission. After the Restoration, he lived precariously on the Continent, flitting about from place to place, but in 1677, a pardon was procured him from Charles II., and he returned to his native country. Nevertheless, he was still obdurately republican in his opinions, and it is undoubted that he schemed for the overthrow of the monarchy, and the establishment of a republic in its stead; for this end he solicited the

aid of the French monarch, and there is evidence of his having been supplied with money by Barillon, the French ambassador. Obscurely his designs were suspected, and in June 1683, when the Rye House Plot was announced, the opportunity was seized to get rid of a man felt to be dangerous. Along with his friend Lord Russell and others, he was arrested, and committed to the Tower. On the 21st November, he was tried for high treason before the brutal Jefferies, and on the merest mockery of evidence, found guilty, and condemned to die. On the 7th of December he was beheaded on Tower Hill. He met his death with heroic firmness, amid general sympathy and indignation. He has ever since enjoyed a sort of canonised reputation as a patriot hero and martyr, and it cannot be held undeserved, narrow and impracticable as we must admit his views to have been. In the history and theory of government, S. was more deeply learned than any man of his time. His *Discourses concerning Government* were first published in 1698; in 1704, another edition was issued, a third appeared in 1751, and the fourth in 1772. S.'s life has been written by S. W. Meadley (Lond. 1813). See also Blencower's *Sidney Papers* (Lond. 1813).

SIDNEY SUSSEX COLLEGE, Cambridge, was founded in 1598 by Lady Frances Sidney, Countess of Essex, or rather by her executors, in obedience to the instructions of her will. They obtained of Queen Elizabeth a mortmain for the purpose, and purchased of Trinity College the site of the ancient convent of Franciscans, or Gray Friars. There are 13 fellowships.

SI'DON (Hebr. Zidon, perhaps 'fishing-place'), anciently, a city of Phœnicia, situated on the east coast of the Mediterranean, in lat. 33° 34′ 5″ N., 45 miles south of Berytus. It was built on a rising mound, protected by the sea on the north and west; while the bed of a river formed a natural fosse to the south, and the high hills shielded it to the east; a double harbour gave shelter to its ships both in summer and winter. It soon rose, both by its exceptional position and the daring and enterprising character of its inhabitants, to the highest rank among the cities of Phœnicia (q. v.), so that the whole country is sometimes designated by the name of S., 'the Great,' 'the Metropolis.' The extensive commerce of S. is well known from ancient authorities. Its colonies extended over the coast of Asia Minor and the adjacent islands, the coast of Thrace and Eubœa, and even some parts of Sicily, Sardinia, Spain, the coast of Cornwall and the Baltic shores, the northern parts of Africa, and, in fact, nearly the whole of the ancient world. Their manufactures of glass and linen, purple dye and perfumes, were sources of unbounded wealth; and, whether they were the skilful workers, or merely the exporters and traders of those 'divine' works in gold and silver, ivory and bronze, which were the marvel of both Greeks and Hebrews, so much seems certain, that they managed to be considered unanimously the most skilful workmen of their time. Although one of the cities assigned to the Israelites by Joshua, it never in reality belonged to them, but, on the contrary, was every now and then in arms against them, either singly, or in league with some of their deadliest enemies, and even subjugated them for a time. After being conquered itself by Tyre, the daughter-city, it attempted to throw off the yoke at the invasion of Phœnicia by Shalmanezer, to which king it surrendered. Under Assyrian, Chaldean, and Persian domination, it retained a kind of independence for its internal affairs, and under the Persians, actually reached its highest prosperity. But an unsuccessful revolt against that power, under Ochus, ended in its temporary ruin (351 B.C.). Speedily rebuilt and repeopled, it opened its gates to Alexander the Great (333 B.C.), and from that time forth it fell successively into the hands of Syrian, Greek, and Roman rulers. Through the middle ages, little is heard of it, except that it was taken by the Crusaders. During part of the 17th and 18th centuries, it again became an important place of commerce; but misrule and violence put an end to its rising prosperity, and the number of its inhabitants has sunk to about 5000. There is still some little export of silk, cotton, and nut-galls. It is now called Saida, occupies a place somewhat to the west of the ancient city, and belongs to the Turkish pashalic of Acre. See PHŒNICIA.

SIE'BENBURGEN (Seven Boroughs), the German name of the Austrian crown-land of Transylvania (q. v.).

SIE'BENGEBIRGE, a collection of conical heights in Rhenish Prussia, on the right bank of the Rhine, about 22 miles above Cologne. The highest of the peaks is the Löwenkopf or Löwenberg, 1560 feet high; but the most famous is the Drachenfels (q. v.).

SIEGE (Fr. a seat, a sitting down), is the sitting of an army before a hostile town or fortress with the intention of capturing it. With certain elements, the success of a siege is beyond doubt; the result being merely a question of time. These elements are: first, the force of the besiegers shall be sufficient to overcome the besieged in actual combat, man to man. If this be not the case, the besieged, by a sortie, might destroy the opposing works, and drive away the besiegers. The second element is, that the place must be thoroughly invested; so that no provisions, reinforcements, or other aliment of war can enter. The third element is, that the besiegers be undisturbed from without. For this it is essential that there shall not be a hostile army in the neighbourhood; or if there be, that the operations of the besiegers be protected by a covering army able to cope with the enemy's force in the field. The ancients executed gigantic works to produce these effects. To complete the investment, they built a high and strong wall around the whole fortress; and to render themselves secure from without, they built a similar wall facing outwards, beyond their own position. The first was circumvallation, the second contravallation. It was thus that Cæsar fortified himself while besieging Alexia, and maintained 60,000 men within his ring. In modern warfare, it is considered preferable to establish strong posts here and there round the place, and merely sentries and videttes between.

Let us now assume that a fortress of great strength has to be reduced, and that the force of the enemy in the vicinity has been either subdued or held in check by a covering army. By rapid movements, the place is at once invested on all sides. This step constitutes merely a blockade; and if time be of little importance, is a sufficient operation, for hunger must sooner or later cause the fortress to surrender; but if more energetic measures are required, the actual siege must be prosecuted. Advantage is taken of any hidden ground to establish the park of artillery and the engineers' park; or if there be none, these parks have to be placed out of range. The besieging force is now encamped just beyond the reach of the guns of the fortress; and their object is to get over the intervening ground and into the works without being torn to pieces by the concentrated fire of the numerous pieces which

the defenders can bring to bear on every part. With this view, the place is approached by a series of zigzag trenches so pointed that they cannot be enfiladed by any guns in the fortress. In order to accommodate the forces necessary to protect the workers, the trenches at certain intervals are cut laterally for a great length, partly encircling the place, and affording safe room for a large force with ample battering materiel. These are called *parallels*, and they are generally three in number. The distance of the first parallel will increase as small-arms become more deadly; but with smooth-bore muskets it has been usual to break ground at 600 yards from the covered-way of the fortress, while in the case of Sebastopol, ground was broken at 2000 yards. The engineers having, by reconnaissances, decided the locality of the parallel, and taken advantage of any inequalities of surface, a strong body of men is sent to the spot soon after nightfall. The attention of the garrison is distracted by false alarms in other directions. Half the men are armed cap-à-pie, and lie down before the proposed parallel; while the other half, bearing each pick and shovel, and two empty gabions, prepare for work. Each man deposits the gabions where the parapet of the trench should be. He then digs down behind them, filling the gabions with the earth dug out; and, after they are filled, throwing it over them, to widen and heighten the parapet. Before daylight, the working-party is expected to have formed sufficient cover to conceal themselves and the troops protecting them. During the day, they—being concealed from the garrison—widen and complete their parallel, making it of dimensions sufficient to allow of wagons and bodies of troops with guns passing along. During the same night, other parties will have been at work at zigzags of approach from the depôts out of range to the first parallel, which zigzags will be probably not less than 1000 yards in length. The profile of a completed trench is shewn in fig. 1, the shaded

Fig. 1.—Profile of a Trench.

portion representing a gabion. As a rule, the defenders will not expend ammunition on the first parallel, for its extent (often several miles) will render the probability of doing material damage extremely small. For this reason also, the dimensions of the parapet and its solidity are of far less importance in the first parallel than in the more

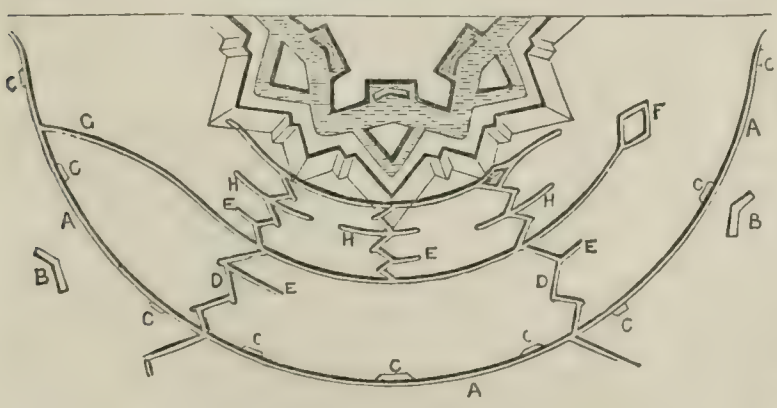

Fig. 2.—Siege Works.

advanced works of attack. The first parallel, AAA, fig. 2, being completed, the engineers select points near its extremities, at which they erect breast-works, B, B, to cover bodies of cavalry, who are kept at hand to resist sorties from the garrison. The length of the parallel is usually made sufficient to embrace all the works of two bastions at least. Sites are then chosen for batteries, C, C, which are built up of fascines, gabions, sandbags, and earth. They are placed at points in the parallel formed by the prolongation of the several faces of the bastions, ravelins, and other works of the fortress, which faces the batteries are severally intended to enfilade by a ricochet fire. Other batteries will be formed for a vertical fire of mortars. By these means it is hoped that the traverses on the hostile ramparts will be destroyed, the guns dismounted, and the defenders dispersed, before the final approaches bring the assailants to the covered-way. The sappers will now commence their advance towards the points, or salient angles, of the two bastions to be attacked. If, however, the trench were cut straight towards the fortress, its guns could easily destroy the workmen, and enfilade the approach. To prevent this, it is cut in short zigzags—as at D—the direction always being to a point a few yards beyond the outmost flanking works of the garrison. The side of each trench nearest the fortress is protected by gabions and sandbags, as in the case of the parallel. At intervals, short spurs of trench, incipient parallels, are cut, as at E, to contain small-arms-men, to act as guards to the sappers. The second parallel is about 300 yards from the enemy's works, and has to be more strongly formed than the first. It often terminates in a redoubt, F, to hold some light artillery, and a strong force of infantry, who could assail any sortie in flank; or it may run into the first parallel, as G, giving easier access for troops than through the zigzags. The second parallel is revetted with sandbags, in which loopholes are left for musketry. After passing the second parallel, the angles of the zigzags become more acute, to prevent enfilading. At about 150 yards, certain demi-parallels, H, are cut, and armed with howitzer batteries, to clear the covered-way, while riflemen also act from it. The third parallel is at the foot of the glacis. Thence the place, after being sufficiently battered, is taken by a storming-party, who make their way over the glacis, or the covered-way is topped by the double sap, as in fig. 3; which is a safer plan for the army generally, though much more deadly to the sappers. When the crest of the covered-way has thus been reached, batteries of heavy artillery will be there established, for the purpose of breaching the walls of the ravelin and bastion; while at the same time miners will first seek to destroy the defenders' counter-mines (which would otherwise be likely to send these batteries into the air), and then will excavate a tunnel to the ditch, at the foot of the counterscarp. If the breach becomes practicable, a storming-party will emerge from this tunnel or gallery, and seek to carry the opposite work by hard fighting. If inner works still subsist, which would tear assailants to pieces, the double sap may be continued across the ditch, if a dry ditch, right up the breach, that counter-batteries may be formed. If the ditch be wet, means must be adopted for a causeway or a bridge. By these means, however obstinate may be the defence, if the besieging force be sufficiently strong, and aid do not arrive from without, the ultimate success of the

Fig. 3.—Double Sap.

attack becomes certain. Vauban raised attack to a superiority above defence, first, by the introduction of ricochet fire, which sweeps a whole line; and secondly, by originating parallels. Before his time, the whole attack was conducted by zigzag approaches; in which the troops actually in front could be but few, and were therefore unable to withstand strong sorties of the garrison, who, in consequence, frequently broke out and destroyed the works of the besiegers, rendering a siege an operation of a most uncertain character.

SIEGE-ARTILLERY is heavy ordnance used for battering purposes, and of too weighty a character to take the field. A siege-train of guns and their ponderous ammunition is usually maintained in the rear of an army, ready to be brought up for use when required.

SIE'GEN, a manufacturing town of Prussia, in Westphalia, stands on the Sieg, 38 miles south-south-west of Arnsberg. In 1868, it had 10,047 inhabitants, who are engaged in manufacturing leather, cotton, and woollen goods. S. is also said to produce the best iron in the west of Germany. In the vicinity are numerous iron mines and smelting furnaces. Its iron and steel wares are noted; especially its files, of which 400 different sorts are said to be manufactured.

SIEGFRIED. See NIBELUNGENLIED.

SIE'NA, a city of Central Italy, 60 miles south of Florence by railway. Pop. 21,902. It is situated on three little hills, separated from each other by three valleys, and higher than the other hills which surround them. Its climate is on this account very salubrious, notwithstanding the deficiency of water caused by its elevated position; to remedy which, subterranean aqueducts had been excavated, five miles in length, some of them dating as far back as the Roman dominion. Its environs are not beautiful, consisting of naked clay-hills, capped with sandstone, but the city is surrounded by trees and avenues, which have a fine effect. The handsome square, Piazza del Campo, is one of the finest in Italy. Eleven streets lead out of it, and it is surrounded by handsome buildings. In this square there is also the famous tower called the *Mangia*, of prodigious height; there are also other towers here and there, seen from a great distance—remnants of the habitations of the feudal lords. The streets are narrow, some paved with tesselated bricks, and others flagged. There are many ancient Gothic palaces, not remarkably handsome. In the Piazza del Campo stands the Palazzo Pubblico, built in the 13th c., in which there are magnificent rooms, and paintings by eminent artists. S. has a fine cathedral, erected, it is said, on the foundations of the Temple of Minerva, begun in 1059; the façade built in the 13th century. It is faced with black and white marble, and is covered with ornaments and sculptures. The pavement is of marble tesselated, representing many biblical subjects. In the different chapels, and in the baptistery, there are frescoes, paintings, and statues, by a number of distinguished masters. The other churches are also rich in works of art. Of the many oratorios, the most noteworthy is that of St Catharine (q. v.), occupying the house of the saint. S. is an archiepiscopal see. There are numerous manufactories of woollen goods, as also of leather and of paper; and in its neighbourhood there are many marble quarries. There is a university, founded in 1330, famous especially as a school of medicine, which has sometimes as many as 200 students. It revived greatly after the abolition of the university of Pisa, in 1849. The Italian spoken at S. is reckoned among the purest.

S. was founded as a Roman colony in the time of Julius Cæsar, under the name of Sena, or Sena Julia. There are no remains of antiquity; and it does not appear to have been a place of any consequence until the middle ages, when it became one of the powerful city republics of Italy. It embraced the Ghibelline cause, and in conjunction with the forces of Pisa, defeated the Tuscan Guelfs, in the memorable battle of Monte Aperto (1260). At the height of its greatness, it is said to have contained 200,000 inhabitants. S. produced a 'school' of artists, of whom the most distinguished names are Guido da Siena, Simone Memmi, Sodoma, Beccafumi, and Baldassare Peruzzi.

SIENNA EARTH. See BURNT SIENNA.

SIE'RRA, a name applied in Spain, and in countries in which the Spanish language has prevailed, to a ridge of mountains. The word means *saw*, and is descriptive of the notched or saw-like skyline of certain mountain-ranges.

SIE'RRA LEO'NÉ (Mountain of the Lion), a British colonial settlement on the Sierra Leone coast, Western Africa. The settlement consists chiefly of a peninsula, about 25 miles long, from north to south, and 12 miles broad; but several islets, as the Isles de Loss and the Banana Islands, belong to it. Area, according to the latest government returns, 300 sq. m.; pop. in 1867, 41,497, of whom 129 were white, the remainder (the males and females being nearly equally divided) were coloured. The peninsula is bounded on the N. by the Sierra Leone river, and on the S. by Calmont Creek and Yawry Bay. Along the coast stretches a belt of rich low-lying land, and elsewhere in the colony there are fertile tracts; but the interior is a mass of rugged mountains, with a generally barren soil. The climate is humid and unhealthy—the wet season, lasting from May to November, being specially pestilential. Tropical fruits and plants grow luxuriantly in the more favourable regions, and coffee, sugar, indigo, and cotton have been introduced by the British. In 1868 the exports amounted to £296,467, the chief articles being bennie-seed, ginger, gum copal, ground-nuts, palm-oil, hides, palm-nuts, and timber. In the same year, the imports amounted to £295,827, and the chief articles were ale and porter, flour and biscuit, cotton and woollen goods, gunpowder, ready-made apparel, hardware, haberdashery, and rum and tobacco. In 1860 there were 71 schools, attended by 11,016 children. The revenue amounted to £59,272, and the expenditure to £55,694. In 1860, 773 vessels, of 101,526 tons, entered and cleared the ports. The colony is divided into numerous parishes, ministered to by about 20 clergymen, and superintended by the bishop of Sierra Leone. The government rests in the hands of a crown-appointed governor, assisted by a council, of a very limited number of members.

The settlement of S. L. was established in 1787, when 470 destitute negroes were removed to it from London by a body of philanthropists; and 1196 negroes were sent to it from Nova Scotia—the climate of which had proved too severe for them—in 1790. The population was also increased by other bands of people of colour; and after the abolition of the slave trade in 1807, the slaves captured by British cruisers have been put ashore, and settled here. In 1820, the settlement contained only 12,000 inhabitants, or less than a third of its present population.

SIERRA MA'DRÉ, a name given to central portions of the great chain of Cordilleras or Rocky Mountains, in Mexico, from lat. 19° to 25° N., and in New Mexico, to the great western range, from lat. 34° to 38° N. These ranges, but partially

explored, contain some of the richest silver mines in the world.

SIERRA MORE'NA, a mountain-range in Spain, on the southern border of New Castile, and between the modern provinces of Ciudad Real and Jaen. It separates the upper portions of the basins of the Guadiana on the north, and of the Guadalquivir on the south, and rises in its highest point to 5500 feet above the sea. It is frequently mentioned in *Don Quixote*, and is the scene of many of the incidents therein described.

SIERRA NEVA'DA (*Snowy Range*), a mountain-range of Spain in Andalusia, extending east from Padul, 12 miles south of Granada, to the frontiers of the modern province of Almeria, is 60 miles in length, from 20 to 30 miles in breadth, and covers an area of upwards of 1000 square miles. It is continued on the north-east by the Sierra de la Filabras, and forms a portion of the watershed between the streams that flow into the Mediterranean and those that flow into the Atlantic. The peak of Mulhacen reaches a height of 11,678 feet, and is the highest summit not only of the Spanish Peninsula, but of the whole of Europe west of the Alps. The peak of Veleta is 11,387 feet high. The range receives its name from the perpetual snow which covers the highest summits. The views from the summits, from which, on the south, may be seen the faint outline of the African coast, on the north, the jagged sierras of the Castiles, can hardly be surpassed in beauty and magnificence by any in Europe.

SIERRA NEVADA, a range of mountains in California, forming a portion of its eastern boundary, is the source of a multitude of rivers, which swell the Sacramento and San Joaquin. The range extends from north-west to south-east 450 miles, and is united to the coast-range, which runs parallel with the Pacific, by Mount San Bernardino. Among the higher peaks of the S. N. are Saddle Peak, 7200 feet high; Table Mountain, 8000 feet; and the Buttes, 9000 feet. Here are immense deposits of gold quartz, with steam and water power crushing-mills; deep tunnels and mines, increasing with their depth their yearly product.

SIEYÈS, Emmanuel Joseph, Comte, who, as the Abbé S., prominently figures in the history of the French Revolution, was born at Fréjus, May 3, 1748. He was educated at the university of Paris with a view to his entering the church; and on the completion of his studies, he obtained the appointment at Treguier, in Bretagne (1775), whence, in 1780, he was transferred to the cathedral of Chartres, of the diocese of which he became chancellor and vicar-general. He had early imbibed the extreme liberal opinions on all matters social and political which were preparing the French Revolution; and when, in 1789, the States-general were summoned, he issued his famous pamphlet, entitled *Qu'est-ce que le Tiers Etat?* This work, which claimed for the people political recognition, naturally enough obtained an immense popularity for its author, and procured his election as one of the deputies for Paris. Mainly through his urgency and influence it was that, on June 16, 1789, the representatives of the people took the decisive step of constituting themselves into an independent body, and became the National Assembly. Of this body he continued for some time to be one of the most prominent and leading figures. In 1791, he was elected to the Legislative Assembly, then convened, as member for the department of Paris. By this time, however, he had sunk somewhat from his first pre-eminence; bolder and fiercer spirits had passed him in the race for power and popularity, and where he had once led, he now reluctantly followed. In the Convention of 1792, to which he was elected as deputy of the department of La Sarthe, he prudently refrained from any active participation in the debates, and on the occasion of the king's trial, he recorded a silent vote. Whilst Robespierre and his party were in power, he consulted his safety by retiring from Paris. When afterwards asked what he had done during the Reign of Terror, he quietly replied: *J'ai vécu* ('I have lived'). On the fall of Robespierre, he returned to his post in the Convention, and resumed his active interest in affairs, becoming a member of the new Committee of Public Safety. He was engaged chiefly in the department of foreign policy, and he went as ambassador to Holland and Berlin successively to negotiate treaties of alliance. He became a member of the Directory in 1799, and among other reactionary measures, he succeeded in closing the celebrated Jacobin Club. Perceiving that a stable government was on no other terms possible, he became anxious to secure the co-operation of some powerful military leader, the more particularly as he was ambitious above all things of giving France a 'constitution' (of which he had drawn up one or several); and on the return of Bonaparte from Egypt, he entered into a league with him, the result of which was the revolution of the 18th Brumaire (November 9, 1799), and the institution of the Consulate, S., Napoleon, and Roger Ducos being the three first consuls. Speedily, however, S. discovered in his new ally his master. As to the distribution of power in the new constitution to be formed, he and Napoleon differed irreconcilably; the man of bayonets was the stronger; his political nostrums never got beyond the paper on which they were written; and finally, in disgust at the subordinate position into which he found himself about to sink, S. threw up his place in the government. As a reward of his services, he received on his retirement a sum of 600,000 francs and the estate of Crosne; afterwards exchanged for the equivalent of a splendid hotel in Paris and the lands of Fainanderie, in the park of Versailles. Also the title of Count was conferred upon him. Subsequently, the presidency of the Senate was offered him, but he declined it, and never afterwards concerned himself in public affairs. Banished at the Restoration, he did not return to France till after the revolution of 1830; and in Paris, on June 20, 1836, he died. During the revolution, S. drew up a good many papers of one kind and another; but he is chiefly remembered for his plan of a new constitution, which, however, is very little known. Mignet's *Histoire de la Révolution* contains a description of it; and under the title of *Théorie Constitutionnelle* of S., and *Constitution de l'An VIII.*, M. Boulay (de la Meurthe) published (Par. 1836) from S.'s own *Mémoires inédits* a more detailed account.

SIGHING, The Act of, is nothing more than a very long-drawn inspiration, in which a larger quantity of air than usual is made to enter the lungs. This is continually taking place to a moderate degree, and Dr Carpenter remarks that it particularly occurs when the attention is released, after having been fixed upon an object which has strongly excited it, and which has prevented our feeling the insufficiency of the ordinary movements of respiration. Hence this action is often a simple result of deficient aëration; while in other cases, as is universally known, it is excited by a depressed state of the feelings.

SIGHT, Defects of. Under this head we shall consider such affections of the eyesight as are due to some known or unknown peculiarity of the

optical apparatus (including the optic nerve) not dependent on disease—viz., *short-sight*, *long-sight*, *double vision*, *colour-blindness*, and *night-blindness*.

Short-sight, *near-sight*, or *myopia* (derived from the Greek words *myo*, I close, *ōps*, the eye), is often popularly confounded with dim or weak sight; but in reality, short-sight applies exclusively to the *range* and not to the *power* of sight, and a short-sighted person may possess the acutest power of vision for near objects. In this affection, the rays which ought to come to a focus upon the retina converge to a point more or less in front of it. The cause of this defect probably differs in different persons. It may arise from over-convexity of the cornea or the lens, from undue density or abundance of the humours of the eye, from elongation of the globe in its antero-posterior diameter, or from an imperfect power of the eye to adjust itself to objects at various distances. The distance at which objects are perceived most distinctly by the perfectly normal eye ranges from 16 to 20 inches; an eye which cannot perceive objects distinctly beyond 10 inches may fairly be regarded as short-sighted; and in extreme cases, the point of distinct vision may be three, two, or even only one inch from the eye. Short-sight is frequently hereditary in families. As a general rule, the inhabitants of towns are much more liable to it than persons living in the country, and students and literary men are the most liable of all. While in the Foot-guards, consisting of nearly 10,000 men, 'not half-a-dozen men have been discharged, nor have a dozen recruits been rejected on account of this imperfection, in a space of 20 years, in one college at Oxford no less than 32 short-sighted men (or *myopes*, as they are termed by some oculists) were met with out of 127' (Donders, *On the Accommodation and Refraction of the Eye*, London, 1864, p. 342). The frequency of this affection in the cultivated ranks points directly to its principal cause—tension of the eyes for near objects. The myopia depending, as Donders believes, upon prolongation of the visual axis, this eminent physiologist inquires: 'How is this prolongation to be explained? Three factors may here come under observation: 1. Pressure of the muscles on the eyeball in strong convergence of the visual axes; 2. Increased pressure of the fluids resulting from accumulation of blood in the eyes in the stooping position; 3. Congestive processes in the base of the eye, which, leading to softening, give rise to extension of the membranes. That in increased pressure, the extension occurs principally at the posterior pole, is explained by the want of support from the muscles of the eye at that part. Now, in connection with the causes mentioned, the injurious effect of fine work is, by imperfect illumination, still more increased; for thus it is rendered necessary that the work be brought closer to the eyes, and that the stooping position of the head, particularly in reading and writing, is also increased. Hence it is that in schools where, by bad light, the pupils read bad print in the evening, or write with pale ink, the foundation of myopia is mainly laid. On the contrary, in watchmakers, although they sit the whole day with a magnifying-glass in one eye, we observe no development of myopia, undoubtedly because they fix their work only with one eye, and therefore converge but little, and because they usually avoid a very stooping position.'—*Op. cit.*, pp. 343, 344.

So far from short-sightedness improving in advanced life, as is popularly believed, it is too frequently a progressive affection; and every progressive myopia is threatening with respect to the future. 'If,' says Donders, 'it continues progressive, the eye will soon, with troublesome symptoms, become less available, and not unfrequently, at the age of 50 or 60, if not much earlier, the power of vision is irrevocably lost, whether through separation of the retina from the choroid, from effusion of blood, or from atrophy and degeneration of the yellow spot.'

In the treatment of myopia the principal objects are: 1. To prevent its further development and the occurrence of secondary disturbances; and 2. By means of suitable glasses, to render the use of the myopic eye easier and safer.

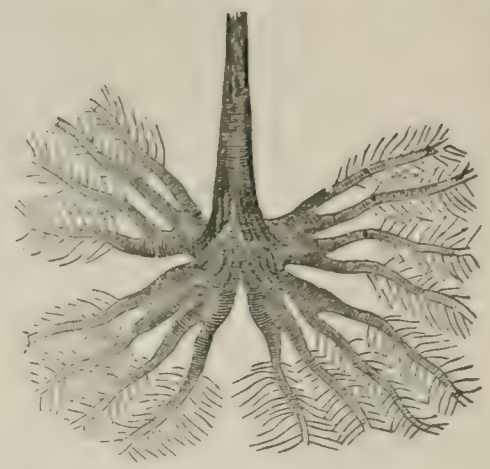
1. To effect, if possible, the first object, the patient must look much at a distance, but as we cannot absolutely forbid his looking at near objects, spectacles must be provided which render vision distinct at from 16 to 18 inches. Moreover, it is desirable that at intervals of a half hour work should be discontinued for a couple of minutes, and no working in a stooping position should be permitted. The patient should read with the book in the hand, and in writing should use a high and sloping desk.

2. The optical remedy for short-sight obviously consists in concave glasses of a focus suited to the individual case. At first sight, it might be supposed that glasses with a concavity exactly sufficient to neutralise the defect in the eye, would always suffice; and when the glasses are used exclusively for distant vision (for example, in the double eye-glass, which is only at intervals held before the eye), or when the affection is slight, and the eye is otherwise healthy, perfect neutralisation is admissible; but so many circumstances forbid the complete neutralisation of the myopia, that an oculist of reputation should always, if possible, be consulted as to the choice of spectacles. Glasses, if injudiciously selected, usually aggravate the evil they are intended to remedy; and in connection with this subject, we must warn our readers against the prevalent habit of employing a single eye-glass; it is most prejudicial to the eye which is left unemployed, and often leads to its permanent injury.

Long-sight and *presbyopia* (derived from the Greek words *presbys*, an aged person, and *ōps*, the eye), are usually considered by English writers as synonymous terms. Donders, who is now universally accepted as the highest authority on this department of eye-affections, maintains that 'the term presbyopia is to be restricted to the condition in which, as the result of the increase of years, the range of accommodation is diminished, and the vision of near objects is interfered with.' As from youth up to extreme old age, the vision of near objects becomes progressively more and more difficult, it is impossible to fix any limit as the commencement of presbyopia. In practice, however, a word is required which indicates the condition in which the eye, at an advanced period of life, and sometimes sooner, requires convex spectacles for distinct near vision, as, for example, for reading, and this word is *presbyopia*. In this state, the nearest point of distinct binocular vision is found to lie about 8 inches (or double the ordinary distance) from the eye, and at this point Donders arbitrarily places the commencement of presbyopia. This condition, which is as natural a concomitant of advanced life as gray hairs or wrinkles, is occasionally met with in young persons. In these cases, it generally arises from intestinal irritation, and may be a precursor of amaurosis; hence such cases should be carefully watched. In ordinary presbyopia, the defect is at once remedied by the use of glasses of low convex power, as of thirty or twenty-four inches focus, which should, however, only be worn during reading and writing, and not constantly. Although the improper use of convex glasses is not by any means so dangerous as the inconsiderate use of concave glasses, the advice of a

good oculist regarding the choice of spectacles is well worth his fee.

Double vision, or *diplopia*, is of two kinds. It may arise from a want of harmony in the movements of the two eyes, the vision of each eye singly being perfect; or there may be double vision with one eye only. The first form may occur (1) in cases of squinting, or (2) in cases of paralysis of one or more of the muscles of the orbit. In cases of Squinting (q. v.), the vision of the most distorted eye is almost always imperfect; and it is well known that impressions on the two retinæ are similar in kind but dissimilar in form. The mind takes cognizance only of the former; so that a person with a bad squint sees objects with the sound eye only. But if the sight of both eyes is nearly equal, as often is the case when the squint is not very well marked, double vision results whenever both eyes are employed together, in consequence of images of nearly equal intensity falling on non-corresponding parts of the two retinæ. This variety of double vision, although annoying, is perfectly harmless. When double vision arises from muscular paralysis, disease of the brain of a serious nature is to be apprehended, although the affection sometimes appears to arise from exposure to cold. The second form of double vision—viz., double vision with a single eye, is a much more rare affection than the preceding one, and depends upon some irregular refraction of the cornea or lens.



Colour-blindness is noticed under its own name.

Night-blindness, or *hemeralopia* (from the Greek, signifying 'day-sight'), is a peculiar form of intermittent blindness, the subjects of which see perfectly with an ordinary light, but become entirely and almost instantaneously blind as soon as twilight commences. It is seldom met with in this country except among sailors just returned from tropical regions. It is frequent among the natives of some parts of India, who attribute it, as our own sailors do, to sleeping exposed to the moonbeams. The most probable cause of the affection is, however, exhaustion of the power of the retina from over-excitement from excessive light, so that this organ is rendered incapable of appreciating the weaker stimulating action of twilight or moonlight. All that suggests itself in the way of treatment is to protect the eyes from strong light during the day, and to prescribe quinine and a nourishing mixed diet.

Snow-blindness must be regarded as an allied affection to the preceding.

SIGHT OF A GUN. See GUNNERY.

SIGILLA'RIA, a genus of fossil plants which are of importance because of their singular structure, and their remarkable abundance in the coal measures. They seem to have contributed more than any other genus of plants to the formation of coal. The roots of S. are found preserved in the shale which forms the floor of all coal-seams. These roots were originally supposed to be distinct plants, and have received the generic name of Stigmaria. The most feasible notion, and that generally accepted regarding them, was that they were fleshy water-plants, with numerous linear leaves, articulated to the stem by papillæ, which were buried in deep cylindrical hollows in the stem. Brongniart first suspected that they were roots, and Binney placed the question beyond doubt by discovering a specimen in which the trunk of a S. rose from the crown of a Stigmaria. Several observers have subsequently seen these fossils also in actual contact. It is believed that the mud (now converted into shale) in which they grew was very soft, and easily permitted the passage of the large roots, while they gave off all round innumerable large hollow rootlets. The stems of S. are abundant in the coal-beds. They are marked by parallel longitudinal flutings, and regular scars formed by the base of the leaf-stalks, which had fallen off. They are known to have attained a height of 70 feet, and a diameter of 5 feet. The stem rose without branching till near the summit, where it branched several times dichotomously. The proportion of woody matter to cellular tissue in the stem was very small. The

Trunk of Sigillaria rising from the Stigmaria Roots (*E. W. Binney*).

woody fibre is characterised by the abundance of scalariform vessels, similar to those which occur in *Lepidodendron*, and in the recent vascular Cryptogamia. The stem is seldom found preserved so as to exhibit any structure, or even its cylindrical form; it generally occurs as a double layer of coal, shewing on the outer surfaces the scars produced by the bases of the leaf-stalks. The form and arrangement of these scars have been used to distinguish the species, and, indeed, no other materials exist, for hitherto no foliage of any kind has been certainly found connected with the trunks. The restoration of the genus has been consequently quite imaginary. Some, with Brongniart, have supposed that the trunk terminated in a crown of simple leaves, like that of many palms, and that it was a gymnosperm near to the Cycads. Others, with King, consider that the fronds of *Pecopteris nervosa*, which are very abundant in the coal measures, are its foliage, and they would restore it so as to have the appearance of a modern tree-fern. And others, with Binney, consider that its affinities are nearer to *Lepidodendron*, and that some of the numerous fragments which have been referred to this genus may really be the branches of Sigillaria. They would restore it as if it were a huge *Lycopodium*, and refer to it some of those fruits which, under the names of *Lepidostrobus* and *Flemingites*, have been described by Brown, Hooker, and Carruthers.

SIGISMUND, emperor of Germany (1411—1437), was the son of the Emperor Karl IV. He was well educated, and having married Maria of Anjou, on her accession to the throne of Hungary he became chief administrator of that kingdom. The death of his wife in 1392 made him king of Hungary; and at the head of a numerous army of more than 100,000 men, composed of Hungarians, French, Germans, and Poles, he attempted to relieve the Byzantine empire from the fierce Turks, but was terribly defeated at Nicopolis (28th September, 1396). On his return to Hungary, he found on the throne a new monarch, Ladislas of Naples, who imprisoned him (1401); but through the good offices of his elder brother, Wenceslas, he was freed,

and obtained the throne (1402), rewarding his elder brother by snatching from him his kingdom of Bohemia, which he retained for some time. In 1411, he was proclaimed emperor, on the death of Rupert. He was present at the Council of Constance, which he had prevailed upon Pope John XXIII. to hold for the purpose of putting an end to the Hussite and other schisms. He contented himself with protesting against the violation of the imperial safe-conduct which was given to Huss, and ultimately consented to his judicial murder, for the purpose, as his apologists say, of conciliating the council, and so settling the disputes concerning the papacy. His succession to the throne of Bohemia, after his brother's death, was opposed by the Hussites, who were now in insurrection; and after a fruitless attempt to conquer them, he confined himself to the defence of Hungary against the Turks, whom he defeated in a great battle near Nissa (1419). For ten years afterwards, he left Germany very much to the guidance of its self-willed petty rulers, who speedily brought the country into such a deplorable state that they were glad to beseech S. to return to the helm of affairs—which he did, but with little good effect. He obtained, by concessions to the Calixtines (q. v.), the crown of Bohemia in 1436; but when he found himself firmly seated on the throne, he gradually withdrew these concessions, which provoked such discontent, that his death, 9th December 1437, alone averted a civil war. S. left one daughter, Elizabeth, who, by her marriage with Albert V. of Austria, brought Hungary and Bohemia to the House of Hapsburg. S. possessed a large intelligence, and remarkable political talents, but these were much neutralised by his impetuosity, indecision, selfishness, and extraordinary avarice; and his well-meaning endeavours after peace and improvement ended in nothing.

SIGISMUND, worthily surnamed the GREAT, king of Poland, was the youngest son of Casimir IV., and was born at Kuzmínek, 1467. He was chosen Grand Duke of Lithuania, 1506, and succeeded to the kingdom of Poland on 8th December of the same year. The affairs of Poland and Lithuania were at that time in a sad condition: the southern portions of the country reduced almost to a desert by the ravages of the Tartars, while the east was continually in dread of the Russians, who had become an independent, united, and powerful monarchy. The Russians invaded Lithuania, and conquered some provinces, but S. gained a brilliant victory over them at Orsza on the Dnieper (14th July 1508). Bogdan, Prince of Moldavia and Wallachia, now invaded the southern provinces, as that semi-barbarous race were accustomed to do without let or hindrance; but he was so decisively routed on the banks of the Dniester, that he gladly agreed to acknowledge himself a vassal of Poland. Disregarding the suggestions of the pope to head a crusade against the Turks, S. next read the Tartars, through his general, Ostrogski, a very forcible lesson, in 1512, against aggressive practices, which cost them 27,000 men, and assured the tranquillity of his frontier for a long period. His alliance in 1513 with Stephen Zapolí, voyvode of Transylvania, whose daughter, Barbara, he also married, alarmed the Emperor Maximilian, who incited the Russians to resume their aggressions, which that ill-advised nation cheerfully agreed to do; paying dearly for their rashness, for their army of 80,000, which had invaded Lithuania, was met and cut to pieces (8th September, 1514) by Ostrogski, with 32,000 men, at Orsza, leaving its standards, cannons, and other arms, 2 generals, 37 princes, 6000 prisoners, and 30,000 dead in the possession of the enemy. Subsequent invasions of Muscovites and Tartars were repelled as before, and a rebellion of the Wallachs was punished by numerous defeats, chief of which was that of Obertyn (1531). The insolence of the Teutonic Order, who had invaded Polish Prussia, was effectually chastised by S., who defeated their Grand Master Albert, his own nephew, in two great battles, in the latter of which the knights were assisted by the Danes (1520). In 1525, he agreed to confer on Albert the title of Duke of Prussia (now known as East Prussia), on condition of fealty and homage. The dukes of Prussia continued as vassals of the Polish crown till 1657. In 1526, S. alone of the monarchs of Christendom lent aid to Hungary against the formidable army of Solyman the Magnificent, and a numerous force of Polish cavaliers fought bravely on the fatal field of Mohacz (1526). The only other important event of S.'s reign was the introduction and extension of Lutheranism in Poland, a change which S. did nothing to prevent, only taking precautions, and sometimes severe ones, against its affecting the civil and political condition of the country. It is told of him that, when John Eck exhorted him to take severe measures with the Lutherans, whom he compared to goats among the sheep ('the faithful Catholics'), S. replied that he was desirous of being 'king of goats as well as king of sheep.' After a long and glorious reign, S. died at Cracow, 1st April 1548, leaving the character of a just, wise, and magnanimous prince, who had restored to his country its ancient prosperity, and had raised it from the very feet of its enemies to a worthy superiority over them.

SIGNALS are the means of transmitting intelligence to a greater or less distance by the agency of sight or hearing. Incomparably the most powerful medium yet known for this purpose is the electric current. See TELEGRAPH. Sound signals have obviously but a short circuit. The electric current requires fixed apparatus establishing an actual communication between the two points; and is therefore inapplicable to the ordinary cases of ships interchanging signals with each other or with the shore; and, except under unusual circumstances, it would not apply to armies manœuvring in the field. For these purposes, so far as present knowledge extends, signals by sight or sound must always be principally the resort.

The ancients seem to have elaborated a fair system of night-signals by torches for military purposes; but in naval affairs the ships sailed so close together, that orders could be communicated by word of mouth, while the turning of a shield from right to left sufficed as sailing directions to the several lines. In modern times, signalling between ships has become indispensable; but there is probably no department of practical science in which progress has been slower, and every so-called system of signals has been distinctly without any system whatever. In the time of James II., a signal could only be expressed by flags, in confusing number, hung in different parts of the vessel. By the commencement of the present century, thanks to Sir Home Popham and other inventors, the system had been adopted of hanging a number of flags under one another, each symbol or combination having an arbitrary conventional meaning attached to it. Alterations in the specific flags have been made from time to time, but essentially this is the system now in use. The flags are either square, triangular of the same length, or pendants which are pointed and longer. These are of black, white, red, blue, and yellow (in the Austrian service alone green is added) in mass or in combination. Specimens of the flags in use in the present naval

code are shewn in fig. 1. The signalmen find, however, that at a distance blue, red, and black are not readily distinguishable, nor yellow from white.

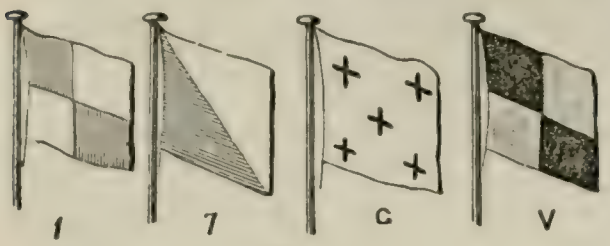


Fig. 1.

It has consequently been the recent tendency, and apparently most justly, to reduce all the signs to black and white, singly or in combination, trusting to shape for different signals.

There are, however, disadvantages attending flags. In a still day, they are difficult to read; or the wind may so blow that they are only seen end on. At sea, the motion of a ship will generally neutralise these drawbacks; but the case is otherwise on shore, and it may consequently occur that the ship can communicate to the land, but cannot get a reply. To obviate this, signals representing solid figures are sometimes employed. To fulfil their conditions, they must appear the same in whatever lateral direction seen. But this limits the shapes to cylinders, cones, and the sphere, or combinations of those figures; and as the total number of distinguishable signs is reduced, signalling becomes reduced from the word-signal to the telegraph. This distinction should be clearly understood, as much is involved in it. A word-signal, as in the present system, is where the whole word or message is sent up at once, and flies simultaneously; a telegraph signal is one in which the letters composing the word or numbers representing the signal are shewn separately, and each is removed before another is shewn. At sea, the word-system is best, for it involves no act of memory; and memory, even from signal to signal, is found difficult by signalmen in the turmoil of perhaps storm or fighting. On the other hand, the telegraph system involves far simpler apparatus, and the changes can be effected more rapidly. As regards the actual time required for a message, the word-system has the advantage in a message short enough for the whole to be shewn at one time; but otherwise the difference is not material. If all advantages be balanced, it is probable that the telegraph system will eventually supersede the other entirely. Whether the word or the telegraph system be practised, another question is, whether to spell each word, or to use numerals and a code. Under the latter principle, about 14,000 of the words and sentences most commonly sent are arranged for easy reference in the signal-book. With the addition of 1 or 2 repeating symbols, the 9 numerals and 0 give combinations 4 together to this number. A combination of figures is arbitrarily assigned to each expression; and the expression is communicated by representing those figures in their proper order. With the book of reference at hand, and intelligent signalmen, there can be no doubt of the superior rapidity of the 'code.' A code has also this further advantage, that the signals representing things and not words, it can be made international, the same symbols representing the same idea in every language. It is then only necessary for universal signalling that each nation should concur in the meaning to be attached to the several signs. Many gentlemen of ability have devoted their attention of late years to the simplification of signals; among whom conspicuous positions must be assigned to Colonel Grant, Captain Bolton, Mr Redl, and Lieutenant Colomb, R.N. Their principal object has been so to simplify the telegraph system that signals may be made with any apparatus, or without apparatus at all. To accomplish this, they have, to a great extent, abjured colour, and resorted to form and motion. Among the form telegraphs there is the principle of the old Semaphore (q. v.), in which each letter or number is shewn by the position of two arms, as in fig. 2. The arms are heavy, and involve mechanism; besides which they are not always clear on a ship in motion beyond a short distance. Very superior in visibility and simplicity is Redl's System of Cones. This consists of 4 cones fixed to a mast. The cones are collapsable, and are formed in a similar manner to umbrellas. Their usual condition is shut, and they can only be held open while a rope attached to each is pulled. With cones of 3 feet base, signalling is rapid and clear up to 5 miles, and the mast can be inserted at any place. The system is very simple: each cone represents a number, 1, 2, 3, or 4; then 1 and 4 shewn represent 5; 2 and 4, 6; and so on, as in fig. 3. This very elegant system can be applied in military

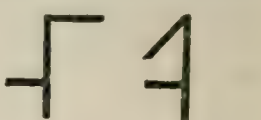

Fig. 2.—Semaphore System.

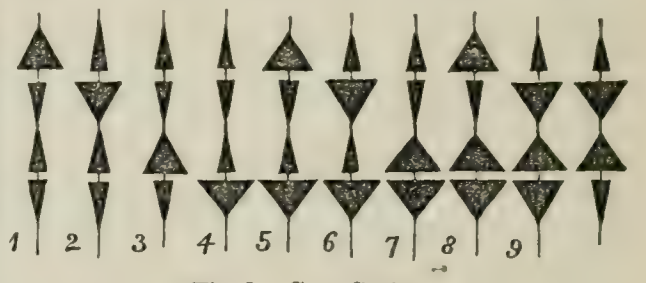

Fig. 3.—Cone System.

or naval operations. But its chief beauty is, that a person understanding it can make the same signals without the cones; for example: if a black flag represent an open cone, and a white flag a shut cone, a ship with 4 black and 3 white flags can make every signal. Again, the arm raised horizontally may represent the open cone; against the body, the shut cone; then two men standing on a cliff are as good as any signal-post, see fig 4. Or if one person

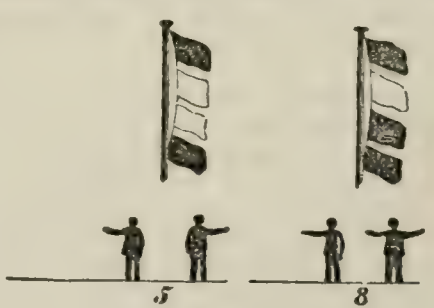

Fig. 4.

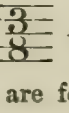
only be present, he may represent an open cone by raising his arm with a handkerchief extended, and a shut cone by his arm without the handkerchief. He has only then to raise his arm four times in quick succession, with or without the handkerchief, to make the required signal. We have thus arrived at a universal system of the utmost simplicity, which in war, and especially during invasion, might be of inestimable benefit to the nation. The code of signals cannot be too generally diffused by the government, in order that every man among the public

may become an amateur signalman on emergency. A secret code, in which the same numbers have different significations, could always be maintained for state purposes.

It only remains to apply the same system to night-signals. The old naval principle has been to hang dingy lanterns in various shapes—triangles, squares, crosses, &c. Besides requiring large bases to be at all visible, this has been found from the motion of a ship to be nearly useless. Redl's system has been applied by hanging four lanterns in a vertical line to represent the cones, and obscuring those which corresponded to shut cones. An improvement was found in introducing a red or green light in the middle, to shew the relative position of the four. The best night-signals are, however, flashing lights, as introduced by Captain Bolton, and more elaborately by Lieutenant Colomb, and adopted in the navy. This consists of a bright light, covered by a shade, which shade, by mechanism, can be lifted for any given time, exposing the light meanwhile. A flash of about half a second's duration is negative: a line of 1½ seconds, positive. Four exhibitions of the light then represent a symbol as in Redl's cones. If the same nomenclature be adopted we should signal as in fig. 5. It will be seen at once that this system produces results similar to Morse's Electric Telegraph. If the distance be

Fig. 5.

within a mile or so, and the weather still, a bugle will answer equally well, long and short notes representing the positive and negative cones.



The fundamental principle of the foregoing system of universal telegraphy, applicable by night or by day, by sight or by sound, is to employ two signals only—one positive and one negative—and to regulate their exhibition by periods of time.

SI'GNATURE, in Music. In writing music in any key with sharps or flats, the sharps and flats belonging to the key, instead of being prefixed to each note as required, are placed together immediately after the clef on the degrees of the staff to which they belong; and this collection of sharps or flats is called the signature. The signatures of the several keys generally in use are as follows:

The minor keys take the same signature with the major keys a third above them.

When a new key is introduced in the middle of a piece of music, the signature of the former key must be contradicted, and that of the new one appended. Thus a transition from the key of D major to that of D minor, is indicated thus:  ; from B major to B minor:  ; the sharps which are to continue being, in this last case, for distinctness' sake, appended in addition to the contradiction of those that are to be discarded. A transition to another key, which is not to continue for any length of time, is seldom indicated by a change of signature; but the sharp, flat, or natural sign is appended to any note as required, that sign affecting all the following notes of the same letter in the measure in which it occurs, unless contradicted. A sharp, flat, or natural thus introduced is called an accidental. Two accidentals are required in the ascending scale of every minor key, to sharpen the sixth and seventh of the tonic.

Besides the signature of the key, a signature of time precedes every musical composition. It consists of two figures placed over one another as a fraction, the denominator 2, 4, 8, or 16 standing for minims, crotchets, quavers, or semiquavers (i. e., halves, fourths, &c. of a semibreve), while the numerator points out how many of these fractional parts of a semibreve are contained in each measure. Thus,  indicates that there are two crotchets, and  three quavers, in the measure. When there are four crotchets (or a semibreve) in the measure, it is usual to write  instead of 

SIGNATURE, in Printing, denotes the letters which are placed at the bottom of the first page of each sheet of a book, to facilitate the arrangement of the several sheets in the volume. The letters employed are those of the alphabet, with the exception of J, V, and W, three letters which have been invented since the use of signatures was introduced. See Alphabet. As the first sheet of a work, containing the title-page, dedication, preface, &c., is generally printed last, the letter A is reserved (along with small letters, *a*, *b*, &c., should there be more sheets of introductory matter) for this, and the signatures commence with B; after reaching Z, they commence again at the beginning of the alphabet, the letter being doubled for the sake of distinction, as AA, or A*a*, or more frequently 2A. Should the alphabet again be exhausted, 3A, 3B, &c., are next employed, and so on. This is the method employed in Britain; in France and Italy, figures are generally used. Signatures (as B2, B3, &c.) are also placed on certain pages of the same sheet, as a further direction to the bookbinder.

SIGNET, in England, one of the seals for the authentication of royal grants. Prior to 1848, all letters-patent and other documents which had to

pass the Privy Seal, required first to have the signet affixed, and passed from the Signet-office to the office of the Privy Seal in the form of signet bills, verified by the signet-seal and superscription and the signature of the Clerk of the Signet. By act 11 and 12 Vict. c. 82, however, warrants under the royal sign-manual, countersigned by one of the principal secretaries of state, have been made *per se* sufficient authority for the Privy Seal to be affixed, and the Signet-office has been abolished. The signet in Scotland is a seal which seems to have been originally intended to authenticate royal warrants connected with the administration of justice. The principal class of agents or attorneys in Scotland are called Writers to the Signet, it is said from their having been originally clerks in the office of the Secretary of State, by whom writs passing the signet were prepared. See WRITERS TO THE SIGNET.

SIGNING, SEALING, and DELIVERY of a deed, in English Law, is the mode of executing a deed. The main acts are, however, the sealing and delivery, for signature is not absolutely essential—at least in some kinds of deeds known to English law. The use of the seal is an ancient form of authenticating deeds, still kept up in England, though long superseded in Scotland by simple subscription. In practice, a wafer or seal is attached to the end of the English deed, and the party who executes it must, after signature, put his finger on the seal, and say: 'I deliver this as my act and deed,' at the same time handing the deed to the person who is to have the custody thereof.

SIGN-MANUAL, ROYAL, the subscription of the sovereign, which must be adhibited to all writs which have to pass the Privy Seal or Great Seal. When attached to a grant or warrant, it must be countersigned by one of the principal secretaries of state, or by the Lords of the Treasury. The sign-manual, in practice, consists but of the initial of the sovereign's name, with the letter R added, for *Rex* or *Regina*.

SIGOURNEY, MRS LYDIA HUNTLEY (Huntley being her maiden name), American authoress and poet, was born at Norwich, Connecticut, in 1791. She was, like most young ladies of ability in New England at that period, early engaged in teaching, and much of her early writings consists of tales, essays, instructive letters, and poems, for her pupils and the young. Her first published work was a volume of poems in 1815. In 1819, she was married to Mr Charles Sigourney, a merchant of Hartford. In 1822, she published a descriptive poem on the *Traits of the Aborigines of America;* and in 1824, a *Sketch of Connecticut Forty Years Since.* These were followed by *Pocahontas and other Poems, Lays of the Heart, Tales in Prose and Verse*, &c. In 1840, Mrs S. visited Europe, and on her return, with a freedom common to American authors, wrote her *Pleasant Memories of Pleasant Lands.* She compiled amusing and instructive books for the young, and was a constant contributor to magazines and other periodicals of poems, whose subjects, style, and sentiment gave her the designation of 'the American Hemans.' She died at Hartford, June 1865.

SIHU'N. See JAXARTES.

SIKHS. The term Sikh, a corruption of the Sanscrit *s'ishya*, signifying 'disciple,' is applied to a community of which the Punjab, in Northern India, constitutes, substantially, the confines. Less commonly, even among themselves, the members of this community are also known as Sinhs (vulgarly Singhs), that is, 'lions,' a title given them by Govind, the last and most influential of their hierarchs. Every name of a Sikh male now terminates with the word Sinh.

Originally a body of mere religionists, the Sikhs, what from the energy which they developed under repression, and the inducements to join them which they offered as proselytisers, grew, by degrees, in strength and numbers, and ended in a formidable nationality. Their originator, Nânak, was born in 1469, in the vicinity of Lahore, and died in 1539, not far from the place of his nativity. To him succeeded, in turn, nine pontiffs, each of whom, like himself, is popularly denominated guru, or 'teacher.' These were Angad, Amardâs, Râmdâs, Arjunmall, Hargovind, Harrây, Harkrishna, Teghbahâdar, and, finally, Govind.

The aim of Nânak was pointedly humanitarian, and designed to combine Hindus and Mohammedans, at the cost of what he held to be only unimportant compromise, into one harmonious brotherhood. Sufficient proof of the comprehensive character of his scheme is afforded by the circumstance that he accepted concurrently the incarnations of Neo-Brahmanism and the mission of the Arabian prophet. His three immediate successors, while zealously protecting the interests of the infant sect, avoided secular pursuits, and held themselves aloof from political complications. Arjunmall, however, not content with signalising himself as compiler of the *Âdigranth*, and as founder of Amritsar, the holy city of the S., engaged with ardour in trade, and rendered himself conspicuous as a partisan of the rebellious Prince Khusrû, son of Jahângîr. Hargovind, who came after Arjunmall, called the S. to arms, led them in person to battle, and, though he remitted nothing of his assiduity as a guru, became an active and useful, though sometimes refractory, adherent of the Great Moghul, against whom his predecessor had plotted. Harrây subsequently espoused the part of Dârâ Shukoh, when contending with his brothers for the throne of India. Harkrishna, son of Harrây, died a child, and was only nominally a guru. Teghbahâdar, after a career of turbulence, was executed as a rebel, by command of Aurangzeb, at Delhi. However deficient in the qualifications demanded for spiritual leadership, it can scarcely be doubted that he contributed, to an important degree, in preparing for the complete change of Sikhism which was effected by his son, Govind. The chief motive that instigated Govind, the tenth of the 'teachers,' to bring about this change was, with some probability, a desire to avenge the ignominious death of his father. He resolved to combat the Mohammedan power and, in deviation from the principles enunciated by Nânak, the Mohammedan religion as well. But Hinduism, with its social restrictions of caste, its fantastic fictions, and its irrational idolatry, likewise fell under his ban. God, he inculcated, is not to be found save in humility and sincerity. In what measure he was a man of thought is evinced by his legacy to his co-religionists, the second volume of the Sikh scriptures. A Sikh, it is therein taught, is to worship one God, to eschew superstition, and to practise strict morality, but equally is to live by the sword. The purport of this last injunction is unmistakable. Govind was assassinated, while in the imperial service, in 1708, on the banks of the Godâvarî. He died, it is true, without beholding the fulfilment of the purpose for which he had striven; but he had, nevertheless, succeeded in stirring his followers to an ambition for political independence—an idea which was ultimately transformed into a reality. His successor, but only as a temporal leader, Banda, suffered a cruel death. He did but little to advantage his sect; and his memory is not held in reverence.

With the decline of the Moghul Empire, the might of the S., in spite of their intermittent reverses, steadily increased, until, in 1764, they convened a general assembly, formally assumed the character of a substantive nation, and issued coin from which the name of the emperor was omitted. Their commonwealth was still denominated, as it had been by Govind, Khâlsa; and the component states of the federation, ordinarily said to have been twelve in number, were thenceforward distinguished as Misls. Foremost in influence among these states was that of Sukarchakiyâ, the chieftain of which was Mahâ Sinh, for whose son, the famous Ranjit Sinh (Runjeet-Singh, q. v.), it was reserved to consolidate the Misls into a unity subject to his own undivided control. The virtual headship of Ranjit Sinh dates from the year 1805, though it was not until 1838 that he attained the zenith of his ascendency. He died in the year following, at the age of 59. During 1845 and 1846, the S. ceased to exist as a nation; and their country has since been ruled by the English. Yet every loyal Sikh is still confident that his people is suffering but a transitory depression, and that it is destined to retrieve, and even to surpass, its bygone glory. In the meantime, the reputed son of a wife or concubine of Ranjit Sinh, Dilîp Sinh, is a pensioner of the British government, has professed Christianity, and has taken up his abode in England.

Ethnologically considered, the S. are, in large proportion, of Jât origin; the Jâts, whom some take to be one with the classical Getæ, being a tribe extensively diffused over the north of India. But other Hindus have helped to swell their ranks, and also not a few Mohammedans. The ten gurus are accounted Kshatriyas, or of the second Brahmanical caste, the martial. The descendants of these several races, from intermarriage and other causes, cannot, however, now be discriminated; and there is no division of the multiform population of India that strikes more than the S., as respects physical uniformity. For symmetry and comeliness, and, it may be added, for courage and powers of endurance, the Lions of the Punjab are altogether remarkable.

Nânak's was, undoubtedly, by far the most successful of the repeated attempts which have been made to fuse together the incompatible dogmas of Hinduism and Islamism. None of the authors of these attempts seem, indeed, to have been acquainted with other than the mere surface of the two religions which they would have blended into one. With the Mohammedan, the existence of the Deity as a pure spirit, and his creatorship of the world, are fundamental postulates. On the other hand, the radical doctrine of the Hindu is pantheism, agreeably to which the universe, alternatively God, is a single eternal substance, under the twofold aspect of spirit and matter. These sets of first principles, which Nânak and his fellow-reformers could never have clearly apprehended, are palpably impossible of reconciliation. Without rejecting all that is distinctive of his creed, no Hindu can assent to the theology of Islam; and, conversely, every intelligent follower of the Arabian prophet must be aware that the monism and the metempsychosis of Brahmanism are utterly antagonistic to the leading positions of his own faith. Govind, as we have seen, openly repudiated the notion of amalgamating Hinduism and Mohammedanism. But a critical acquaintance with his real views, in their fulness, and of those of Nânak, must remain a matter of conjecture until we possess a detailed translation, executed by some scholar competently versed in Hindu philosophy, of the *Âdigranth* (The Original Record) and the *Daswîn Pâtsâhî dâ Granth* (The Record of the Tenth King). These voluminous compositions are metrical throughout, and are chiefly in Hindi and Panjâbi; the former containing, additionally, a little Sanscrit, and the latter, a long chapter in Persian. They are written in the same character as the Sanscrit, the values of the letters being altered, though their forms are retained.

Among the numerous divisions into which Sikhism, as a system of belief and practice, has ramified, two, at least, apart from the great central sect, deserve specification. First are the Udâsis, professors of indifference to mundane concerns; a sect whose origin is attributed to S'richand, a son of Nânak. These recluses, whom Amardâs refused to recognise as genuine S., have, to this day, numerous disciples. The Akâlis sprang up just after the time of Govind. For extravagance of fanaticism, these Ishmaelites have, it is hoped, no rivals; and the style of their piety is comparable with that of a Thug.

As specimens of the superstitions of the S., it may be noted that, like the Hindus, they look upon the eating of beef as a deadly offence, and that, like the modern followers of Zoroaster, they attach sinfulness to the act of extinguishing a light with the breath. Some illustrations of practical Sikhism may also be gathered even from the few remarks that have been made touching the gurus. It is not irrelevant to add, that Amardâs humanely discountenanced the cremation of widows, and that Arjunmall committed suicide. The morality of ordinary S. is as positively maintained by one class of writers as it is denied by another. Evidence should seem to shew that the agriculturists among them are much on a par, as to correctness of life, with other Indian cultivators of the soil. As to their soldiers, however, it has been observed that they are deeply tainted with those repulsive impurities for which the Persians are so infamous. Though forbidden the use of tobacco, they are under no restriction as concerns indulgence in bhang, opium, and intoxicating drinks; and it would be gross flattery to commend them on the score of sobriety. As regards morality, there is reason to believe that they have greatly degenerated since the days of Govind.

The gross Sikh population has been most variously estimated by different statisticians, some of whom compute it at considerably less than half a million of persons, while others deem a million and a quarter, or even a million and a half, to be not excessive.

For the most satisfactory extant treatment of the subject of this article, the reader is referred to Captain J. D. Cunningham's *History of the Sikhs*. Sir J. Malcolm's *Sketch of the Sikhs; The Asiatic Researches*, vols. i. and xi.; the collective works of Professor H. H. Wilson, vols. i. and ii.; and *The Calcutta Review*, vols. xxxi. and xxxiii., may likewise be consulted with advantage.

SIKH WARS, two brief but desperate contests waged between the British power in India and the Sikhs in 1845—1846, 1848—1849, which resulted in the destruction of the latter as an independent nation. The first had its origin in the dissensions which convulsed the Sikh country after the death of Runjeet Singh (q. v.), and which necessitated the exercise of a wary regard on the part of the Calcutta authorities. At length an army of Sikhs, flushed with their triumph over all lawful authority in their own country, crossed the Sutlej, and extended their ravages over British territory; but their advanced guard was met by Sir Henry Hardinge, the governor-general, at the head of four regiments of infantry and one of dragoons, and routed at Mudki (q. v.) with heavy loss. Three days after, their main body, which had meantime crossed the river, and intrenched itself at Feroze

Shah (q. v.), was attacked by a larger force of British under Gough and Hardinge, and after a bloody conflict, which lasted two days, also routed. Still undismayed by these reverses, they again intrenched themselves at Sobraon; but a fresh body which had just crossed the Sutlej at Aliwal (q. v.), 19,000 strong, with 68 pieces of cannon, was wholly routed and driven across the river by Sir Harry Smith, at the head of 7000 men, with 32 guns; and their main body was soon after similarly dispersed at Sobraon (q. v.). The British then crossed the river, took Lahore, and restored the authority of the young Maharajah, from whom they took the territory between the Beas and the Sutlej, the treaty confirming this settlement being made at Lahore, 9th March 1846. But the internal disturbances in the kingdom of Lahore soon became as active as before, and induced the Maharajah's prime-minister to put the country under the Company's protection; and a residency with a guard of regular troops was then established in the capital. On April 20, 1848, two British officers were murdered by a Sikh chief, the dewan Moolraj of Multan; and as this was found to be but a premonitory symptom of a general outbreak, a small force of British under Lieutenant Edwardes, aided by a body of Sikhs, under the Rajah of Bhawalpûr, gallantly attacked the army of Moolraj, which, after a desperate conflict of nine hours, they defeated on June 18, and, both sides in the meantime having received reinforcements, again on July 1. Multan was then laid siege to, but the defection of 5000 auxiliary Sikhs under Shere Singh (the son of the Sirdar Chuttur Singh, the governor of Hazara, who had been for some time in revolt, and had driven the British from his district) compelled the British to retreat. For some time, the British authorities in the Punjab were hampered by a want of military force, and though the Maharajah and much of his army still opposed the Sikh rebels, little reliance could be placed upon most of it. Shere Singh now succeeded in raising his army to 40,000, but was defeated by Lord Gough at Ramnugger (November 22). The inconsiderate haste of Gough at Chillianwalla (January 13) nearly lost him that great battle, which was saved only by the extreme valour of his soldiers; but amends for this fault were made at Gujerat (q. v.), where the power of Shere Singh and his allies was completely broken. Meanwhile, the fortress of Multan had, after a protracted bombardment, been captured; and the Company, seeing no other mode of protecting their territories from annoyance by these warlike fanatics, annexed the Punjab, March 29, 1849, thus terminating the existence of the Sikhs as an independent nation.

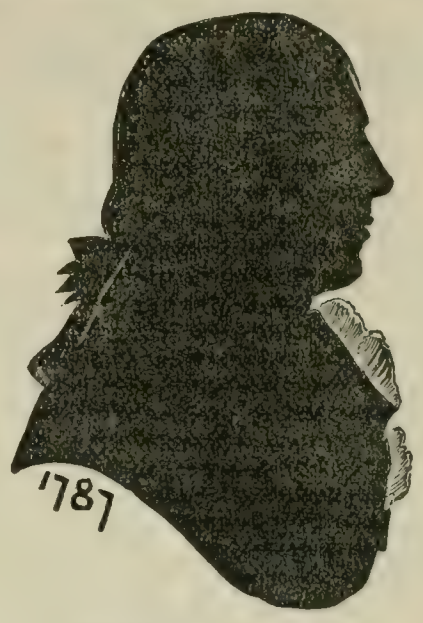
SI-KIA'NG, or WESTERN RIVER, a river at the southern extremity of China Proper. It has lately been ascertained by our surveyors to be navigable for vessels not drawing more than 16 feet of water for about 100 miles from its mouth. The S. is remarkable for the purity and clearness of its waters. It is at present chiefly useful in conveying the sugar-cane that grows in its vicinity, as well as rafts of timber from the forests of Kwangse, to the markets of Canton.

SI'KKIM, a small protected state in the north-east of India, bounded on the W. by Nepaul, and on the S.-E. by Bhotan. Area, 1670 sq. m.; pop. 61,766.

SILE'NÉ, a genus of plants of the natural order *Caryophyllaceæ;* with a tubular 5-toothed calyx; five notched or bifid petals, which terminate in a narrow claw at the base, spring from the stalk of the germen, and have each an appendage forming a *Corona* (q. v.) in the mouth of the corolla; ten stamens; three styles; the capsule 3-celled, 6-toothed, many-seeded. The species are numerous, mostly natives of the temperate parts of the northern hemisphere, annual and perennial plants; nine or ten of them natives of Britain, and others frequent in flower-gardens.—One of the species most common in America, but introduced from Europe, is the BLADDER CAMPION (*S. inflata*), a perennial, which grows in fields and dry pastures, and has a branched stem fully a foot high, ovate-lanceolate bluish-green leaves, panicles of white flowers, and an inflated calyx, with a beautiful network of veins. The young shoots are sometimes used like asparagus, and have a peculiar but agreeable flavour, somewhat resembling that of peas. They are best when most blanched. The cultivation of this plant was long ago strongly recommended, but it has not obtained a place among garden plants.—The MOSS CAMPION (*S. acaulis*) is a pretty little plant, with beautiful purple flowers growing in patches so as to form a kind of turf, one of the finest ornaments of the higher mountains of Scotland, and found also in Cumberland and Wales. —Many species, some of them American, are popularly called CATCHFLY, from their viscidity, as *S. regia* and *S. Virginica*, found in open woods or on the prairies of Ohio, Kentucky, and southwards.

SILE'NUS, son of Pan and Gæa (the Earth), is generally represented as the chief of the Sileni or older Satyrs (q. v.), and the inseparable companion of Bacchus, with whom he took part in the contest against the Gigantes, slaying Enceladus. In most respects he seems to have resembled the other satyrs, and to have borne a strong likeness to Sir John Falstaff, being in addition noted for his wisdom and his power of prophecy. S. had a temple at Elis.

SILE'SIA, a province of the kingdom of Prussia, included in the limits of the new German empire, lies south of the provinces of Brandenburg and Posen, and is bounded on the E. by the Polish provinces of Russia and Austria, and on the S. and W. by the Austrian provinces of Silesia and Bohemia, and the kingdom of Saxony. It is divided into three governments: *Liegnitz*, in the west, *Breslau*, in the east, and *Oppeln*, in the south; and these, again, are subdivided into circles. Total area, 15,547 English sq. m., with a pop. (1867) of 3,585,752, of whom 1,811,805 are Catholics, 1,711,569 Protestants, and 44,822 Jews. Of the population, $\frac{1}{5}$th speak Polish, more than 90,000 employ other Slavic dialects, and the rest use the German language. This province, by far the largest and most populous of the Prussian provinces, is crossed from north-east to south-west by a broad strip of mountainous country, which widens out at each extremity; and along the whole eastern boundary, and in the south, are ranges of low hills; in the north-west and centre, the surface is flat and heathy, or sandy, with numerous stagnant pools. S. is almost wholly included in the basin of the Oder (navigable as far south as Ratibor), which flows through it from south-east to north-west, and receives from each side numerous tributaries; but a small portion in the extreme south is drained into the Vistula, which here takes its rise. The soil is altogether fertile and well cultivated, more so, however, in Lower than in Upper S.; and cereals of all kinds, oil-plants, beet, hops, occasionally vines, and above all, flax and hemp, are the crops of the province; but of late years the cultivation of tobacco, and of plants yielding dye-stuffs, has been receiving increased attention. Cattle and sheep, the latter excellent in quality, and partly of pure or mixed merino blood, are reared in the high-lands, the annual produce of wool averaging fully 140,000 cwt. The mines of S. are of great importance; iron, copper, and lead are the chief



products; coal is found in abundance. The manufacture of lace, averaging in annual value £1,500,000, is carried on in the mountainous districts, chiefly around Schweidnitz; and the production of other fabrics, as linen, cotton and woollen goods, paper, iron, leather, glass, and earthenware, is vigorously carried on throughout the province. The Oder, and the great central railway from Berlin and Posen to Vienna, afford ample facilities for commerce. There are a university at Breslau, gymnasia in the principal towns, and a great number of professional and industrial schools.

S. was inhabited at the beginning of the Christian era by the Quadi and Lygii, who, like the other German tribes, advancing westward in the 6th c., were succeeded by Slavic tribes. It formed part of the Slavic kingdom of Moravia, was next joined to Bohemia, and in the beginning of the 10th c. to Poland. In 1163, it was separated from the kingdom of Poland, but was ruled by dukes who were of the royal line of Piast; these dukes, to repeople the country, which had been devastated by the numerous civil wars, encouraged the settlement of German colonies, especially in Lower Silesia. The practice of division and subdivision of territory prevailed so extensively in S., that at one time it had no less than 17 independent dukes, and to save itself from re-incorporation with Poland, it acknowledged the sovereignty of the kings of Bohemia, with which, and with Germany, from the time of the Emperor Karl IV., it was indissolubly connected. In 1537, the Duke of Liegnitz, one of the numerous Silesian princes, entered into an agreement of mutual succession (*Erbverbrüderung*) with the Elector of Brandenburg, on the extinction of either reigning line; and the other ducal lines becoming gradually extinct, their possessions fell to Liegnitz or to Bohemia, or lapsed to the emperor. In 1675, when the last ducal family, that of Liegnitz, failed, his territories of Liegnitz, Brieg, and Wohlau, would have fallen to Prussia, but the emperor of Germany refused to recognise the validity of the agreement of 1537, and took possession of the Liegnitz duke's dominions, as a lapsed fief of Bohemia. The remainder of S. was thus incorporated into the Austrian empire. In 1740, Frederick II. of Prussia, taking advantage of the helpless condition of Maria Theresa of Austria, laid claim, on the strength of the agreement of 1537, to certain portions of S.; and without declaring war, marched into, and took possession of the province, maintaining his hold despite the utmost efforts of Austria in 1740—1742, and 1744—1745, called the *first* and *second* Silesian wars. After the *third* Silesian war, better known as the SEVEN YEARS' WAR (q. v.), it was finally ceded (1763) to Prussia.

SILESIA, AUSTRIAN, a duchy and a Cisleithan province of Austria, bounded on the N.E. by Prussia, and on the S.W. by Moravia. Area, 1963 sq. m.; pop. (1869) 511,581. It is mountainous in the west, where the Spieglitzer Schneeberge, a summit of the Sudetic chain, rises to the height of 4512 feet. The province comprises 1806 sq. m. of level land, of which by far the greater portion is arable or under wood. The climate, though rough, is healthy, and the soil produces good crops of rye, oats, barley, flax, &c. Within the province rise the Oder and the Vistula. Cattle-breeding and bee-keeping are important branches of industry; 170,000 head of sheep belong to the province. Iron, lead, and coal mining are profitably pursued. The manufactures are principally spirits, copper and iron wares, and linen and cotton fabrics.

SI'LEX (Lat. flint), a generic name given by some mineralogists to all those minerals of which silica is the principal ingredient. See QUARTZ.

SI'LHOUETTE, the name given to a profile or shadow-outline of the human figure, filled in of a dark colour, the shadows and extreme depths being sometimes indicated by the heightening effect of gum or some other shining material. This species of design was known among the ancients, and was by them carried to a high degree of perfection, as the monochromes on Etruscan vases amply testify; but the name S. is quite modern, dating from about the middle of last century. It was taken from Etienne de Silhouette, the French

Silhouette of Robert Burns.

minister of finance in 1759, who, to replenish the treasury, exhausted by the costly wars with Britain and Prussia, and by excessive prodigalities, inaugurated numerous reforms, and the strictest economy of expenditure. His extreme parsimony in all finance matters made him a choice subject for caricature; so that any mode or fashion that was plain and cheap—'surtouts' without plaits, trousers without pockets—was styled *à la Silhouette;* and profiles made by tracing the shadow projected by the light of a candle on a sheet of white paper being then much in vogue, have continued to bear the name. Although without merit as a work of art, the S. presents a clear and well-marked profile, and such instruments as the Pantograph (q. v.), &c., used to be frequently employed to obtain profiles of a reduced size direct from the human features.—Profiles cut out of black paper with scissors also receive the name of silhouettes.

SI LICA. See SILICON.

SI'LICON, or SILI'CIUM (sym. Si, eq. 28, spec. grav. 2·49), is one of the metalloids, or non-metallic elements. It may be obtained in three different forms or modifications—viz., the *amorphous*, the *graphitoid*, and the *crystalline*. It is the first of these, the amorphous silicon, which is obtained by the processes in common use, the second and third being obtained from this first modification.

Amorphous silicon presents the appearance of a dull brown powder, which adheres to the finger, is insoluble in water and in nitric and sulphuric acids, but readily soluble in hydrofluoric acid, and in a hot solution of potash. It is a non-conductor of electricity, and when heated in air or oxygen, its external surface burns brilliantly, and is converted into silica, which fuses from the extreme heat, and forms a coating over the unburned silicon. *Graphitoid*

silicon is obtained by exposing the amorphous variety to an intense heat in a closed platinum crucible. This form of silicon will not take fire when heated in oxygen gas, and resists the solvent action of pure hydrofluoric acid, although it rapidly dissolves in a mixture of nitric and hydrofluoric acids; moreover, as another point of difference, it is a conductor of electricity. For the description of *crystallised* silicon, we may refer to a treatise by Deville (in the *Ann. de Chimie*, 3d ser. vol. 49, p. 65), who obtained it in regular double six-sided pyramids of a dark steel-gray colour.

Silicon, in a state of combination with oxygen, is the most abundant solid constituent of our globe; and, in less proportion, is an equally necessary ingredient of the vegetable kingdom, while in the animal kingdom it occurs in mere traces, except in a few special cases. It is never found in nature except in combination with oxygen; but by a somewhat difficult process—which we need not here describe—it may be separated as a dark brown powder. It was first isolated by Berzelius in 1823. For our knowledge of the other modifications, we are indebted to Wöhler and Deville.

Silicon forms two oxides, one of which is only known in the hydrated state, while the other is the well-known compound, silica or silicic acid. *Hydrated oxide of silicon* is represented by the formula $Si_4O.4H_2O$, and silicic acid by SiO_2. The hydrated oxide exhibits many interesting chemical properties, but is of no practical importance.

Silicic acid or *silica* exists both in the crystalline and in the amorphous form. The best examples of the crystalline form are rock-crystal, quartz, chalcedony, flint, sandstone, and quartzose sand. Silica in this form has a specific gravity of about 2·9, and is only attacked with difficulty by potash or hydrofluoric acid. The amorphous form exists naturally in opal, and is obtained artificially as gelatinous silica, &c.; it differs from the former in its specific gravity, being about 2·2, and in its being rapidly dissolved by potash and by hydrofluoric acid. Pure silica (as it occurs in rock-crystal, for example) is perfectly transparent and colourless, and is sufficiently hard to scratch glass. The heat of the oxyhydrogen blowpipe is required for its fusion, when it melts into a transparent glass, capable of being drawn out into elastic threads. Perfectly pure silica in its amorphous form may be obtained by various chemical processes. If a solution of silicate of potassium or sodium be treated with hydrochloric acid, the silicic acid separates as a hydrate, and on evaporating this to dryness, and treating it with boiling water, silicic acid remains as an amorphous powder, which, after being washed, dried, and exposed to a red heat, may be regarded as chemically pure. The hydrated silicic acid mentioned in the above experiment is soluble in water, and more freely in acids and alkalies. The solubility of hydrated silicic acid in water accounts for the presence of silicic acid in mineral springs and in the Geysers of Iceland, as well as for its gradual separation from these waters in the form of petrifactions. That silica or silicic acid is a true acid (although a feeble one) is obvious from its uniting with bases, especially those which are capable of undergoing fusion and forming true salts, known as silicates. These silicates occur abundantly in nature; all the forms of clay, felspar, mica, hornblende, augite, serpentine, &c. being compounds of this description. Silicic acid combines with bases in various proportions. The following table exhibits the composition of the several groups of natural silicates, with the ratio of the quantity of oxygen contained in the base and acid (SiO_2) in each case:

Name of Group.	Oxygen ratio.	Formula.	Examples.
Hexabasic.	1 : ⅓	$6M_2O.SiO_2 = M_{12}SiO_8$.	Collyrite.
Tetrabasic.	1 : ½	$4M_2O.SiO_2 = M_8SiO_6$.	Staurolite.
⅔ Silicates.	1 : ¾	$8M_2O.3SiO_2 = M_{16}Si_3O_{14}$.	Chondrodite.
Dibasic, or Orthosilicates.	1 : 1	$2M_2O.SiO_2 = M_4SiO_4$.	Olivine.
¾ Silicates.	1 : 1½	$4M_2O.3SiO_2 = M_8Si_3O_{10}$.	Scolerite.
Monosilicates, or Metasilicates.	1 : 2	$M_2O.SiO_2 = M_2SiO_3$.	Wollastonite.
Sesquisilicates.	1 : 3	$2M_2O.3SiO_2 = M_4Si_3O_8$.	Stilbite.
Disilicates, or Bisilicates.	1 : 4	$M_2O.2SiO_2 = M_2Si_2O_5$.	Beaumontite.

In the above formulæ, MO stands for 1 equivalent of any metallic protoxide, such as lime, magnesia, or protoxide of iron.

The following are the general characters of the silicates: Most of them are fusible, the basic silicates fusing more readily than those which are either neutral, or contain an excess of acid. Excepting the silicates of the alkalies, no silicates are soluble in water. The anhydrous, neutral, and acid silicates of the earths resist the action of all acids except the hydrofluoric.

In conclusion, we may remark that silica derives its name from *silex*, flint, of which it is the essential constituent, and that it is largely employed in the manufacture of glass, china, and porcelain. For these purposes, it is obtained in a finely comminuted state by heating flints or portions of colourless quartz to redness, and plunging them in cold water. The silica splits up into a friable mass, which may be easily ground to a fine powder. The use of silica in giving firmness and rigidity to various parts of the animal organs, is exemplified in its free occurrence in the quill-part of the feather of birds, in the shields of certain infusoria, and in the spicula occurring in sponges; while its similar use in the vegetable kingdom is seen in its more or less abundant presence in the stalks of the grasses, more particularly in the cereals and in the bamboo (where it is especially deposited about the joints, and is known as *Tabasheer*), in the equisetæ, &c.

Silicon may be made to combine with several other elements besides oxygen, but, with the exception of silicofluoric acid, these compounds are of no practical value. Thus silicon and hydrogen form a hydride of silicon, a colourless and spontaneously inflammable gas. Nitride of silicon is a bluish fibrous body, while sulphide of silicon is a white earthy powder. Silicon unites with chlorine, bromine, and probably iodine and fluorine, in two proportions corresponding to its oxygen compounds. Fluoride of silicon (SiF_2) is a colourless pungent gas, liquefiable under strong pressure, and solidifying at —220°, inflammable, and a non-supporter of combustion. It is obtained by heating powdered glass with 12 times its weight of oil of vitriol, and when a stream of this gas is transmitted through water, a reaction takes place; two atoms of water and three atoms of the fluoride of silicon yielding silicofluoric acid (SiH_2F_6), which remains in solution, and silicon, which is deposited. A saturated solution of this acid forms a very sour fuming liquid, which does not directly attack glass, but if allowed to evaporate on it, causes erosion from the fluoride of silicon becoming evaporised, and free hydrofluoric acid being left. A dilute solution is frequently employed in the laboratory as a precipitant of potash, which it throws down in a transparent gelatinous form

With salts of baryta, it gives a white crystalline precipitate. It combines with bases to form salts, none of which are of any special importance.

SI'LIQUE (*Siliqua*), in Botany, the fruit of the *Cruciferæ*, a capsule opening by two valves, which, when ripe, separate from the base upwards, leaving a central frame (*replum*), to which the seeds remain attached, and which is regarded as formed by parietal placentas, the valves giving way close to the suture. The seeds are either in one row or two. A SILICULE (*silicula*) is merely a silique of a different form, the true silique being long and narrow, the silicule broad and short, although Linnæus made this difference the foundation of the orders (*Siliquosa* and *Siliculosa*) of his class *Tetradynamia*, a distinction not now equally attended to in the subdivision of the natural order *Cruciferæ*.

SILI'STRIA, a strongly-fortified Turkish town, is situated on the right bank of the Danube, which is here nearly one-fourth of a mile wide, and is studded with numerous islands. The houses are mean, and built generally of wood, though sometimes of stone, and also of mud; the streets, like those of most Moslem cities, are crooked, narrow, dirty, and ill-paved; and the manufactures are insignificant, though there is a considerable trade in wood and cattle. Pop. 20,000. The importance of S. is almost wholly as a military outpost of Bulgaria, for it is the first convenient point for the crossing of the Danube by the Russians, the Dobrudsha or peninsula between the Danube and the sea being well protected from invasion by its deadly climate. Its walls are constructed of solid masonry, but consist merely of a fortified *Enceinte* (q. v.) surrounded by a ditch, the great strength of the fortress depending upon the support given to it by detached works. S. is a town of great antiquity, and was a fortress under the Byzantines. Here, in 971, the Byzantine emperor, John Zimisces, routed the Russians under Sviatoslav. It has been repeatedly assaulted and taken by the Russians. In 1849, S. was made a stronghold of the first class, and was rendered almost impregnable by the addition (1853) of 12 detached forts on the south and east. On the outbreak of the Crimean war, the Russians laid siege to it, with an army of from 60,000 to 80,000 men, while the Turkish garrison under Mussa Pasha amounted to 15,000; and after a vigorous and well-sustained attack of 39 days, the Russians were compelled to retreat, with the loss of 12,000 men.

SILK AND SILKWORM. The name *silk* is derived, by the not unusual substitution of *l* for *r*, from Lat. *sericum* (Gr. *serikon*), so called as coming from the country of the Seres or Chinese. The SILKWORM is the caterpillar of the SILKWORM MOTH, of which there are numerous species belonging to the genus *Bombyx* and other genera of the family *Bombycidæ*, lepidopterous insects of the section popularly known by the name Moth (q. v.). The *Bombycidæ* have a very short and rudimentary proboscis, living for a very short time in their perfect state, and taking little or no food; the body is thick and hairy; the wings are large and broad, either extended horizontally when at rest, or inclined like the sides of a roof; the antennæ are pectinated. The caterpillars feed on the leaves and other tender parts of trees or other plants; the chrysalids are enclosed in a cocoon of silk, which gives to some of the species a great economical importance. The most important is the COMMON SILKWORM (*Bombyx mori*), a native of the northern provinces of China. The perfect insect is about an inch in length, the female rather larger than the male; the wings meeting like the sides of a roof; the colour whitish, with a broad pale brown bar across the upper wings. The females generally die very soon after they have laid their eggs, and the males do not survive much longer. The eggs are numerous, about the size of a pin's head, not attached together, but fastened to the surface on which they are laid

Silkworm Moth (*Bombyx mori*), in its various stages.

by a gummy substance, which, when dry, becomes silky. They are laid in the end of summer, and are hatched in the beginning of next summer. The caterpillar is at first very small, not more than a quarter of an inch in length, but rapidly increases in size, till, when full grown, it is nearly three inches long. It is of a yellowish gray colour. The head is large. On the upper part of the last joint of the body is a horn-like process. The skin is changed four or five times during the growth of the caterpillar. Before each change of skin, it becomes lethargic, and ceases to eat, whereas at other times it is very voracious. When the skin is ready to be cast off, it bursts at the fore part, and the caterpillar then, by continually writhing its body, without moving from the spot, thrusts it backwards; but silkworms frequently die during the change of skin. A very rapid increase of size takes place whilst the new skin is still soft. The natural food of the silkworm is the leaves of the white mulberry, but it will also feed on the leaves of some other plants, as the black mulberry and the lettuce. When so fed, however, it produces silk of inferior quality. The silk-producing organs are two intestine-like tubes containing a viscid substance, which extend along great part of the body, and terminate together in a *spinneret* at the mouth. These vessels become very large when the change to the chrysalis or pupa state is about to take place. When about to spin its cocoon, the silkworm ceases to eat, and first produces the loose rough fibre which forms the outer part of the cocoon, and then the more closely disposed and valuable fibre of its interior. In this process, the position of the hinder part of the body is little changed, but the head is moved from one point to another; and the cocoon when finished is much shorter than the body, which, however, being bent, is completely enclosed in it. The cocoon is about the size of a pigeon's egg. Each fibre of silk, when examined by a microscope, is seen to be double, being equally derived from the two silk-producing organs of the caterpillar. A single fibre often exceeds 1100 feet in length. The time of the silkworm's life in the caterpillar state is generally about eight weeks. About five days are occupied in the spinning of the cocoon; after which about two or three weeks elapse before the cocoon bursts and the perfect insect comes forth. The natural bursting of the cocoon is, however, injurious to the silk, and the silkworm rearer prevents it by throwing all the cocoons into boiling water, except those which he intends to keep in order to the maintenance and increase of his stock. These he selects with care, so that he may have about an equal number of male and female insects, the females being

known, even in the chrysalis state, by their larger size. The cocoons intended for the production of moths are placed on a cloth in a somewhat darkened room, of which the temperature is near, but does not exceed 72° F.; and the moths, when produced, shew no inclination to fly away, but remain on the cloth, lay their eggs, and die there. It is an interesting peculiarity of this valuable species of moth, that neither in the caterpillar nor in the winged state does it shew that restless disposition which belongs to many others, the caterpillars remaining contentedly in the trays or boxes in which they are placed, feeding on the leaves with which they are there supplied, and at last only seeking a proper place to assume the chrysalis form on small bundles of twigs which are placed for that purpose above the trays; the perfect moths, in like manner, abiding almost in one spot, and scarcely caring to use their wings. By this peculiarity it is capable of being reared and managed in a way which would otherwise be impossible.

The silkworm is liable to various diseases, particularly to one by which great numbers are often destroyed, and which is either caused or characterised by the growth of a small fungus known as *Silkworm-rot*, or *Muscardine* (q. v.).

Of the other species of silkworm, many are rapidly increasing in commercial importance. The following is an enumeration of the chief silk-producing insects; those in Italics are not as yet employed in manufactures:

Bombyx mori.—The common silkworm, native of India, and reared in other parts of the world.
B. cræsi.—Crosses have been obtained between this and B. mori, yielding excellent silk, at Mussooree.
B. textor.—Native of Mussooree.
B. sinensis.—China.
B. Huttoni.—Silk collected in Mussooree.
B. Horsfieldi.—Native of Java.
Attacus atlas.—Native of India, and said to yield some of the 'Tusseh Silk.'
A. Guerini.—Native of Bengal.
A. Arrindia.—Castor-oil plant silkworm, a native of Bengal and British India. Wherever the castor-oil plant grows spontaneously, the efforts to raise this worm have been successful.
A. Cynthia.—Ailanthus silkworm, indigenous to temperate China, and lives mainly on the leaves of the *Ailanthus glandulosus*. Long cultivated in China in the open air. Introduced into France in 1858, and, through the efforts of M. Guerin de Meneville, rendered of industrial value.
A. Militæ.—The Tusseh silkworm, found wild in Bengal and the hot regions of India, where its cocoons are gathered from the woods. Attempts to introduce it into France have not been successful.
A. Yama May.—Wild silkworm of Japan, feeds on the leaves of the oak.
A. Cecropia—is found in the middle and southern Atlantic states. It can live on the leaves of the Elm, Willow, &c.; its silk is coarse; it is a tender and delicate worm.
A. Assama.—The Moonga, or Moogha, native of Assam.
A. Pernyi.—North China.
A. Perrottetti.—North China.
A. Roylei.—Mussooree.
A. Helferi.—Darjeeling.
A. Jana.—Java.
A. Frithii.—Darjeeling.
A. Larissa.—Java.
The preceding seven are all called Tusseh moths.
Actias Selene.—Darjeeling.
Saturnia pyretorum.—China.
S. Grotei.—Darjeeling.
Lœpa Katinka.—Java.
Neoris Huttoni.—Mussooree.
Salassa Lola.—South-east Himalaya.

It will be seen by the above list that hitherto very few of the silk-moths have been turned to man's profit. The first in importance after the common silkworm is the true *Tusseh*, next, the *Moonga*, the silk from both of which can be wound off the cocoon; and then the *Eria*, which cannot be wound easily, and is therefore generally carded.

Silk appears not to have been well known to the ancients; although several times mentioned in the translations of the Bible, the best authorities deny that it is in the original, or that it was known to the Hebrews. Among the Greeks, Aristotle is the first who mentions it, and he only says that 'Pamphile, daughter of Plates, is reported to have first woven it in Cos;' and from all the evidence which has been collected, it would appear that the natives of Cos received it indirectly (through the Phœnicians and Persians) from China. The silken webs of Cos found their way to Rome, but it was very long before they were obtainable except by the most wealthy. The cultivation in Europe of the worm itself did not take place until 530 A.D., when, according to an account given by Procopius, the eggs were brought from India (China) to the Emperor Justinian by some monks.

In China, the cultivation of silk is of the highest antiquity, and according to the greatest Chinese authorities, it was first begun by Si-ling, the wife of the Emperor Hoang-ti, 2600 years B.C.

Since its introduction to Europe, it has always formed a great branch of industry in Italy, Turkey, and Greece, and it has been cultivated to some extent in France, Spain, and Portugal.

The quantity of silk raised in the world is enormous. The raw silk produced in China is alone valued at $81,200,000; the production of Italy at $39,200,000; that of France at $25,600,000; of India at $24,000,-

Ailanthus Silkworm (reduced), shewing the Cocoon of Silk attached to a Leaf.

000; Japan, $17,000,000; Turkey, $14,000,000; Spain and Portugal, $3,200,000, and other producers, including America, $80,000—a total of $214,900,000. In 1860 the value of French silks amounted to upwards of $140,000,000, and the exports to $110,000,000. In 1860 the French exported to the United States $20,800,000 of silk; in 1861, over $5,000,000; in 1866, $6,000,000; in 1870, $11,418,033. The American imports of silk from Great Britain in 1870 amounted to nearly $10,000,000; all others, $2,708,567. In 1860 the production of silk goods in the United States, including tram, organzine, &c., was placed at upwards of $5,000,000; that of Philadelphia and New York alone, including ribbons, was valued at $2,300,000. Since 1860 the American silk manufacture has greatly developed. At present (1870) our silk fabrics are competing with European goods, and Philadelphia has 30

silk trimming factories; New York, 50; Paterson, N. J., 15. At Hartford, Conn., one factory employs 1000 hands, and produces 600,000 yards of wide goods, and an immense quantity of belting and spun silk. California promises to become a large producer of silk. Its product in 1869 was estimated at 30,000,000 cocoons.

Rearing of Silkworms.—It is of the first consequence in the production of silk that one of the species of mulberry should be cultivated, and that it should be so favourably situated as to climate, that its foliage is in readiness for feeding the young worms when they are first hatched from the eggs. The species best adapted is the white mulberry, *Morus alba*. The extreme lateness of season at which the black mulberry produces its leaves, prevents its employment generally, besides which it will not bear the loss of its leaves so well. It is said that in some parts of China the silkworm is easily reared upon the trees in the open air. So little has it a tendency to wander far from the place of its birth, if food be at hand, that it only requires a warm dry atmosphere to bring it to perfection; but usually, even in China, and in all other countries, it is thought desirable to raise the silkworm in properly arranged buildings, and to supply it with mulberry leaves gathered from day to day. In India, China, and other tropical countries, the eggs hatch readily at the proper time by the natural heat; but in Southern Europe, artificial heat is almost always required; formerly, the heat of fermenting dung was found serviceable, and the warmth of the human body was also used, the eggs being carried in little bags in the bosom of the cultivators; but now they are regularly hatched by stove-heat, beginning with a temperature of 64° F., which is gradually increased through ten days to 82°, at which it is maintained until the eggs are hatched. Experience has shewn that the operation is facilitated by washing the eggs in the first place with clean water; and some cultivators also wash them in wine, the value of which is very questionable. Washing is found to remove a certain gumminess and other impurities from the eggs, which would otherwise impede the hatching. When the silkworms have been regularly developed as above described, it is usual to place above the trays various little contrivances for the caterpillar to spin within: many of the Italian growers employ an ingeniously simple arrangement, which lasts many seasons, and when not in use, occupies very small space. It consists of a number of thin slips of wood, about an inch and a half broad, and all cut sufficiently long to reach across the trays. They are each cut at intervals of an inch half through, as in fig. 1, so that one will fit into another, as in fig. 2; and when complete, they all form a series of cells, which, set in a tray (fig. 3), form the very best receptacles for the silkworm to spin in. When not in use, the whole arrangement can be compressed into very small compass, as in fig. 4, for convenience of storage. Others use little cones of paper, or small twigs, amongst which the cocoons are spun.

Fig. 1.

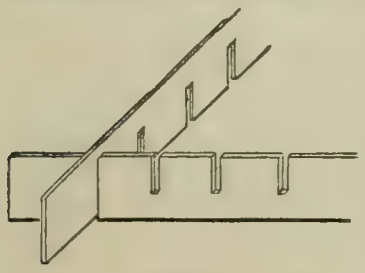


Fig. 2.

In feeding the worms, care is taken so to distribute the food on the shelves or in the trays that the insects shall not crowd together; and for this reason, the most careful cultivators chop the leaves small, and strew them very evenly about. Great care is taken not to let the worms of one hatch mix with those of another, unless of exactly the same age, otherwise the stronger insects would deprive the younger of their food. Many other niceties of attention are required, which altogether render the successful rearing of silkworms a matter of much anxiety and labour.

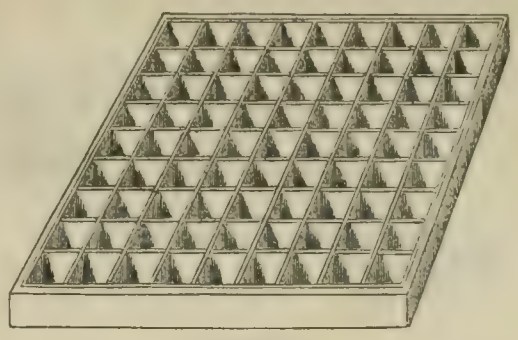

Fig. 3.

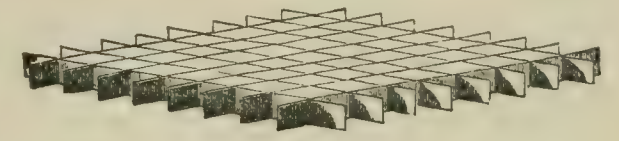

Fig. 4.

Preparation of Silk.—When the cocoons are completed, which is known by the absence of any sound within, they are carefully sorted, and a certain number are kept for laying. The sexes are readily known by the difference of shape as well as of size, the female being plumper, as in fig. 5, and the male (fig. 6), besides being much smaller, having a central depression and sharper extremities. The French growers sort them into nine varieties, those which are less compact, or in which the worm has died—a fact known by external indications—being separated from the good ones. When the sorting is finished, the cocoons are placed in an oven with a gentle heat, which kills the enclosed chrysalis, otherwise they would all become *perforated* by the insect eating through; they are then prepared for winding by first removing the flossy covering, which is often somewhat hard and compact. The cocoons are placed in basins of water, kept warm by charcoal fires, or, in the larger establishments, by steam. This softens and dissolves the natural gum which coats the silk, and makes the various coils of silk adhere together in the cocoon. The operator then takes a small branchy twig, and stirs them about in the water. This is sure to catch hold of any liberated ends which may be floating in the water. From three to five of these ends are taken and twisted together with the fingers, so as to unite them into one thread, which is passed through a polished metal or glass eye in the reeling-machine, which is so far from the hot-water basin as to give the softened gum on the silk time to dry in its passage from the basin to the reel. In large *filatures* or silk establishments, complex machinery is used for winding; but reeling apparatus of the greatest simplicity is used by the Chinese, East Indians, and

Fig. 5.

Fig. 6.

others with almost equal effect, when carefully done, except in the amount of work accomplished. In all cases, however, the principle is the same, and is very simple, as shewn in fig. 7, in which *a* shews the small pan of warm water holding the cocoons,

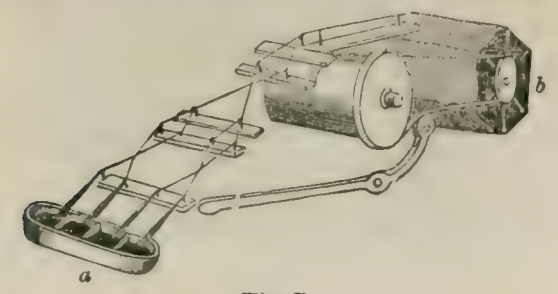

Fig. 7.

the threads from which are gradually united, and wound on the reel *b*. Great care and skill are required in reeling silk from the cocoons, because, although the reeler starts with four or five cocoons, not only are their individual threads apt to break, but they are not all of the same length, so that one will run out before the others. These matters are carefully watched; and as often as a thread breaks, or a cocoon runs out, another thread is joined on, and is made to adhere to the compound thread on the reel by its natural gumminess. Each cocoon generally yields 300 yards of thread, so that it takes 1200 or 1500 yards to make 300 yards of the filament of raw silk, by which name the reeled silk is always known. The raw silk is made up into hanks of various sizes. That from China and Japan is tied in packages of six hanks each, technically called *books*, and sometimes the ends of these books are covered with silken caps very curiously formed out of a single cocoon, so managed as to form a filmy cap sufficiently large to cover a man's head. The method used by the Chinese to accomplish this is quite unknown in Europe. These caps or bags, when closed, are sometimes nearly a foot square, and much of the wadding used by the Chinese dressmakers for padding is made by placing these bags upon each other to the required thickness.

Notwithstanding the care taken in reeling the silk from the cocoons, and forming several threads into one, it is not ready for the weaver, but has to undergo the processes called collectively *throwing*. In this country, this is a special trade, the *silk throwster* usually conducting it in large mills with extensive machinery, where the above processes are all carried on, generally by steam-power. The silk reaches the throwster in hanks as imported. These are put into clean soap and water, and carefully washed, ties having been placed at intervals, to prevent the silk entangling. After being dried by hanging in

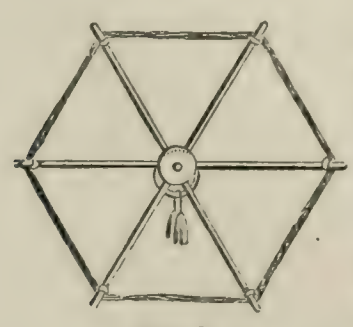

Fig. 8.

Fig. 9.

the drying-room, they are placed on large skeleton reels called *swifts* (fig. 8), so adjusted that they will hold the hanks tightly. Fig. 9 is a front view of a *swift*, and shews that the spokes, *a*, *a*, are in pairs. They are made of thin pieces of lancewood, and each pair are rather nearer together at the axle than at the circumference, where they are connected together by a small band of cord, *bb*. These bands are so tied that they will slip down easily to admit of the hanks being placed; then, by pushing the cords upwards, the hank can be stretched to its fullest extent. This is necessary to compensate for the varying lengths of the hanks received from different countries.

When the *swifts* are set in motion, the silk is carried from the hanks to bobbins, upon which it is wound for the convenience of further operations. The bobbins are then taken from the *winding* to the *cleaning* machine, when they are placed on fixed spindles, so that they will turn with the slightest pull; and the thread is passed through a small apparatus attached to the machine, which is specially called the cleaner, and consists essentially of two polished smooth-edged blades of metal (*a*, *a*, fig. 10), attached to a part of the frame of the machine, *b*. They are held together by the screw *c*, and are slightly opened or closed by the other screw, *d*, so that the thread can be put between them down to the small orifice, *e*, and then, by tightening the screw, preventing its return, after passing through this small hole, which is the gauge of the thread, and which removes any irregularities or adherent dirt. The silk next passes over a glass or metal rod, and then through another small hole, much larger than that of the *cleaner*, and usually made of glass, on to the bobbin, upon which it is wound by the action of the machine. The next process is *twisting* the cleaned thread, by which it becomes better adapted for being combined with other threads. *Doubling* is the next process, and this consists in running off a number of bobbins of *twisted* silk on to one bobbin of a larger size, which is put into the *throwing*-machine, when the ends of the *doubled* silk are passed through a smooth hole on to a large reel, which rewinds it into hanks, but twisting the threads into a fine cord as it goes from the bobbins to the reel. This operation of *throwing* derives its name from the Saxon *thrawan*, to whirl or twist. After this, the hanks have to be again wound on reels and bobbins for the weaver, the former for the warp, and the latter for the weft. For many purposes, only some of these operations are required. Thus for common and light fabrics, such as *Persian*, *gauze*, &c., only the two first are needed—viz., the *winding* and *cleaning*, and the material is called *dumb-singles*. If it has been *wound*, *cleaned*, and *thrown*, it is called *thrown-singles*, and is used for weaving common broad stuffs, or plain silks and ribbons. If *wound*, *cleaned*, *doubled*, and *thrown*, it is called *tram*, and is used for the richer silks and velvets, but only for the weft or shoot; and if *wound*, *cleaned*, *spun*, *doubled*, and *thrown*, it is called *organzine*, and is used for the warps of fine fabrics.

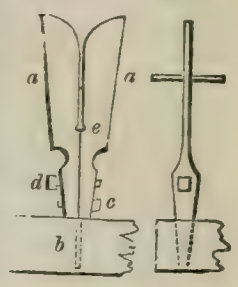

Fig. 10.

Before winding the cocoons, a flossy portion has to be removed; and after all has been wound off, another portion remains, like a compact bag; these are collected and sold under the name of *waste-silk*, and to these are added the fragments of broken threads, which accumulate in considerable quantities during the reeling and throwing operations. Formerly, very little use was made of waste-silk; not a little of it was employed by engineers and others for mere cleaning purposes; although, as early as

1671, a proposition was made by a manufacturer named Edmond Blood to make it available by carding it with teasels or rowing-cards. He took out a patent for this invention, but apparently did not bring it into use. Another patent was taken out for the same thing in 1855, by Louis Narcisse Dupont, and from this time it has been all spun into yarn, thereby greatly economising the use of silk, as the quantity of silk-waste always greatly exceeds the amount of good silk reeled off. The processes employed in the production of silk-yarn from the waste differ little from those for spinning other materials. See SPINNING.

The silk-manufactures of Britain are chiefly located in Spitalfields, London, at Macclesfield and Congleton in Cheshire, at Derby, and in Glasgow. The dyeing of silk is done chiefly in the neighbourhood of London, at Nottingham, and at Manchester. See *Ailanthus Silkworm*, by J. G. Morris, M.D., in *Rep. of Com. of Agriculture*, 1861 and 1862; *Silk and Silk Manufactures*, by E. C. Cowdin, *Rep. of U. S. Com. to the Paris Universal Exhibition*, 1867; Ibid., in *Rep. of Com. of Agriculture* for 1868.

SILK-COTTON. Under this name, various silky fibres are from time to time brought from tropical countries to Europe; they are all of the same general character, and are produced by the trees composing the genus *Bombax* and other genera recently separated from *Bombax*, of the natural order *Sterculiaceæ*, known as silk-cotton trees. These trees are natives of the tropical parts of Asia, Africa, and America. The fibre fills their large woody capsules, enveloping the seeds, and is produced in great abundance; but is too short, too smooth, and too elastic to be spun by the machinery used for cotton; although attempts have been successfully made on a small scale in India to spin and weave it; and that of *Bombax villosum*, which is of a beautiful purple colour, is woven into cloth and made into articles of dress in New Spain. Silk-cotton is much used for stuffing pillows, mattresses, and sofas. Sir James Emerson Tennent says it 'makes the most luxurious stuffing' for them. It has the fault, however, of being easily broken and reduced to powder, but might probably be very useful in the manufacture of gun-cotton and collodion. The silk-cotton of the East Indies is imported into Britain under the name of *Moc-main*. —*Bombax ceiba*, the common silk-cotton tree of the West Indies and South America, attains a very great size, its trunk sometimes being so thick that it could not be encompassed by the outstretched arms of sixteen men, and canoes are hollowed out of it of an average burden of twenty-five tons. The wood is soft and spongy, but is used for many purposes, and when cut into planks, and saturated with lime-water, it bears exposure to the weather for many years.—*Bombax Malabaricum*, or *Salmalia Malabarica*, is the common Silk-cotton Tree of the East Indies. It is a tall tree, covered with formidable thorns. Although it is a tropical tree, its leaves fall annually; and just before the fresh leaves appear, it is covered with crimson tulip-like flowers, so abundant, that 'when they fall, the ground for many roods on all sides is a carpet of scarlet.'

The fibre of the capsules of *Chorisia speciosa* and *C. Pecholtiana*, trees nearly allied to the genus *Bombax*, and natives of Brazil, is known as VEGETABLE SILK. It has a beautiful satiny lustre, and is very light, but no mode of spinning and weaving it has yet been invented.

SI'LKWORM GUT, a material used by anglers for dressing the hook-end of the fishing-line. It is prepared from the silkworm at the period when it is just about to spin, and the sericteria or silk vessels are distended with the secretion. The worms are immersed for twelve or fourteen hours in strong vinegar, and then taken separately, and pulled in two very gently. The skilled operator knows at sight if the soaking in vinegar has been sufficient, and if so, he lays hold of one end of the viscid secretion, which is seen in the silk glands, and attaches it to the edge of a board; the other end he stretches to the other edge of the board, and attaches it with a pin. When a number are drawn across the board, it is set in the sun for the threads to dry, when they are tied into bundles for use. They are chiefly produced in Italy and Spain.

SILL, the horizontal wood or stone base along the bottom of a window or door; also the wooden plate along the bottom of a partition.

SILLIMAN, BENJAMIN, American physicist, was born at North Strafford (now Trumbull), Connecticut, U. S., August 8, 1779. His father was a distinguished lawyer, and a brigadier-general in the War of Independence. He was educated at Yale College, New Haven, in which he was appointed a tutor in 1799, and was admitted to the bar in 1802, but soon after received from the college the appointment of Professor of Chemistry; which he accepted only on condition of visiting some of the seats of learning in Europe, to observe the progress of the science. His tour in Europe, 1805—1806, was one of the first of which an account was published in the United States. Uniting mineralogy and geology to chemistry, he made a geological survey of Connecticut, observed the fall of a meteorite; constructed, with the aid of Professor Hare, a compound blowpipe, and repeated the experiments of Sir Humphry Davy. In 1822, he first established the fact of the transfer of particles of carbon from the positive to the negative electrode of the voltaic apparatus. In 1818, he founded the *American Journal of Sciences and Arts*, better known as *Silliman's Journal*, of which he was for twenty years the sole, and for eight more the principal editor. Besides his labours as professor and editor, he began in America the since widely-extended work of popular scientific education, by giving public lectures on his favourite sciences in all the chief cities. In 1830, he published a text-book on Chemistry, and soon afterwards edited an edition of *Bakewell's Geology*. An account of his last visit to Europe was published in 1851, and reached six editions. His last course of lectures was given in 1855, when his son, BENJAMIN SILLIMAN, jun., who had been his associate, became his successor. He died at New Haven in November 1864.

SILU'RIAN ROCKS, a large division of the Palæozoic rocks between the Old Red Sandstone and the Cambrian strata. They comprise the greater portion of the rocks called by Werner 'transition,' because, as he thought, in their structure they exhibited an intermediate character between Lehman's 'primary' or metamorphic rocks, and the 'Secondary' or fossiliferous deposits. But the fossils peculiar to these beds having been found in rocks without the transition structure, the name has long ago fallen into disuse. The term 'grauwacke' or 'graywacke,' a miners' term, was also introduced from the Germans, and for some time employed to designate these rocks, because of the abundance in them of a compact argillaceous sandstone; but this awkward name has also given place to Silurian, a term introduced by Sir R. I. Murchison when he first established the system, and derived from the district where he investigated the strata, which was the region of the Silures, a tribe of ancient Britons.

The Silurian system contains an enormous thickness of rocks, nearly 30,000 feet, according to some estimates, the absolute thickness being greatly increased by immense beds of interstratified igneous rocks. The upper limit, underlying the Old Red Sandstone, is universally accepted, but there has been considerable diversity of opinion in regard to the inferior boundary. Professor Sedgwick, having described the rocks of North Wales, which at first were considered to be older than the series which Murchison had illustrated, designated them Cambrian. This name has been retained for the immense mass of indurated shales and sandstones of a thickness nearly equal to that of the Silurians, which contain only faint traces of organic life, and underlie the Llandeilo formations. But Sedgwick claims also the Lower Silurian rocks as a portion of this system; the priority of name, and the uniform facies of the organic remains of the whole of the Silurian rocks, have, however, induced geologists to consider the limits as originally given by Murchison as those of the system.

The subdivisions of the rocks of the period are the following:

Upper Silurian Rocks.

	Thickness in Feet.
Upper Ludlow—	
1. Downton Sandstone and Tilestones,	80 to 1000
2. Upper Ludlow Shale,	800
Lower Ludlow—	
3. Aymestry Limestone,	150
4. Lower Ludlow Shale,	900
Upper Wenlock—	
5. Wenlock Limestone,	300
Lower Wenlock—	
6. Wenlock Shale,	1400
7. Woolhope Limestone and Denbighshire Grit,	150

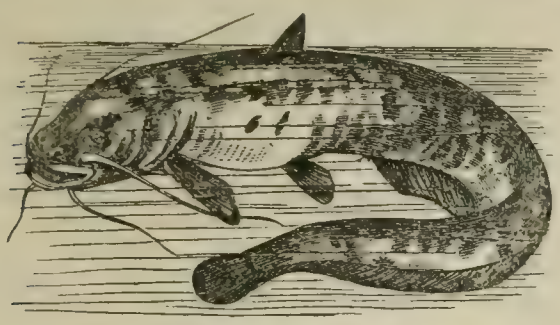
Middle Silurian Rocks.

Upper Llandovery—	
8. Tarannon Shale,	1000
9. May-hill Sandstone and Pentamerus Limestone,	800
Lower Llandovery—	
10. Llandovery Slates,	1000

Lower Silurian Rocks.

Caradoc—	
11. Caradoc Sandstone,	12,000
12. Bala Limestone,	
Llandeilo—	
13. Upper Llandeilo,	1500
14. Lower Llandeilo or Arenig Beds,	
Contemporaneous Volcanic Rocks,	5800

The typical Silurian strata are in Wales, and the adjoining English county, Shropshire. With the exception of the southern and south-eastern districts, where the Old Red Sandstone and Coal Measures occur, the whole of Wales is composed of Silurian and Cambrian rocks. The same deposits are found in Cumberland and the north of Lancashire. The whole of Scotland south of a line drawn from Dunbar on the east to Girvan on the west, consists of graywacke rocks, slates, and limestones of Silurian age, with the exception of one or two small patches of Old Red, Carboniferous, and Permian strata. The rocks, till recently referred to an azoic group, below the lowest fossiliferous strata in the north of Scotland, are now generally believed to be highly altered beds of this period. The southern boundary of these beds is a line drawn from Stonehaven to Helensburgh. A huge trough, filled up with Old Red Sandstone and Carboniferous strata, separates the highly altered strata of the north from the less altered deposits of the south. An extensive region of Silurian rocks occurs in the south-eastern counties of Ireland and in Galway; and a great track of the same beds extends from the centre of Ireland (Cavan, &c.) to the coast of Down. The metamorphic rocks of the north-west are most probably also of the same age as the corresponding strata in the north of Scotland.



On the continent, Silurian strata have been examined and co-related with the British types, in Bohemia, by M. Barrande; in Scandinavia, by M. Angelin; and in Russia, by Murchison and others. In North America, also, extensive regions are covered with these strata. They have been wrought out and their fossils described by the Canadian and United States surveyors. Similar strata have also been detected in India, Australia, and South America.

The life of the period presents a group of very characteristic organisms, which, with the exception of the fish-remains found in the upper beds, all belong to the invertebrata. Many of them are confined to the Silurian rocks, or occur only very rarely in some of the Palæozoic formations. The Graptolites are a strictly Silurian family of Zoophytes, and most of the forms of Trilobites are found only in this period, though some members of the tribe are found in rocks of Devonian and Carboniferous age. Besides these, may also be specified such forms as Heliolites and Favosites among the Corals; Actinocrinites and the Cystidians among the Echinoderms; Orthis and Lingula among the Brachiopods; and Lituites and Maclurea among the Cephalopods.

In all the immense thickness of Silurian rocks, no deposit has been discovered containing organisms that have lived on land. Some fragments have been noticed that have a faint resemblance to the branches of Lepidodendron, and minute bodies occur in the bone-bed, which are referred to the spores of a terrestrial cryptogam. The only other indications of plants are impressions believed to have been produced by sea-weeds. The anthracitic shales of Wales and Scotland probably derived their anthracite from the algæ that must have abounded in the Silurian seas. In Shropshire, a number of shells have been found, whose nearest allies are littoral species, and these appear to indicate the existence there of an ancient shore. The Silurian rocks are, however, generally sea-deposits, and Forbes has ingeniously shewn, from the small size of the conchiferæ, the paucity of spiral univalves, the great number of floating shells and of the pelagic Orthidæ, and the great rarity, or absence, except in the upper beds, of fossil fish, that it is most probable they were deposited in a sea more than 70 fathoms deep.

SILU'RIDÆ, a family of malacopterous fishes, of the order *Nematognathi*, divided into many genera, and including a great number of species, mostly inhabitants of the lakes and rivers of warm countries. The S. exhibit great diversity of form. Their skin is generally naked, but some have a row of bony plates along the lateral line, and a few are completely mailed with bony plates. The dorsal fin is single in some; others have two dorsal fins, the second being sometimes adipose, as in the salmon family. The dorsal fin is sometimes armed with a strong spinous ray, and in most of the family the first ray of the pectoral fins is very strong and serrated, so as to be capable of inflicting a severe wound, and by this these fishes are protected from alligators and other enemies. All have the mouth furnished with barbels, more or less numerous; the two principal barbels being on the upper lip, and formed by elongation of the intermaxillary bones. The barbels are believed to be organs of touch, probably of use in directing the fish to its prey. The bones of the head and other parts of the skeleton exhibit many peculiarities, into which we cannot enter. The S. are generally inhabitants of muddy rivers, lurking amongst the mud. The only European species is the SHADEN (*Silurus glanis*), the largest

of European fresh-water fishes, and sometimes found in the sea near the mouths of rivers. It is not found in the rivers of Britain, France, Spain, or Italy, but it is plentiful in the Danube and the Elbe, and their larger tributaries, also in the rivers which fall into the Caspian

Sly Silurus (*Silurus glanis*).

Sea. It attains a length of six or even eight feet, and a weight of 300 or 400 lbs. In America the S. have a great development. In the Mississippi the *Hopladelus olivaris* reaches a weight of 150 lbs.; in the tributary streams the 'blue cat,' *Ichthœlurus cœrulescens*, a swift species, is valued as food. The eastern rivers abound in species of *Amiurus*, which are extensively eaten. They are mud-lovers. The species of *Noturus* have an eel-like tail, and inflict a severe wound. In Brazil the species are numerous and large. Many are covered with bony scuta, and are armed with serrate spines. Prominent are the *Sorubims*, *Pimelodi*, and *Dorades* (q. v.). Several species of this family are found in the Nile, among which is the KARMOOT (*Clarias anguillaris*), a fish anciently an object of superstitious regard in the Thebaïd.

SI'LVAS, or SELVAS (Span. *selva*, a forest), the name given to the western portion of the great plain of the Amazon, in the north-west of Brazil. The Silvas, which are about one-third of the whole plain, contain more than 700,000 English sq. m., and consist of low land on a dead level, densely covered with primeval forests, and annually inundated by the overflow of the mighty river or its tributaries. The forests are rendered wholly impenetrable from the denseness of the underwood, matted together as it is by creeping and climbing plants, which form myriads of festoons glowing with nature's brightest tints. The vegetation of the Silvas, under the stimulating action of the abundant irrigation, the intense tropical heat, and the inconceivable richness of the alluvium which constitutes the soil, shews an exuberance of growth far surpassing that of any other portion of the earth's surface, and from its very luxuriance, presents a bar to civilisation no less effectual than do the barren deserts of Africa or the gloomy wastes of Central Asia. The few Europeans who have penetrated into this region have sailed up the Amazon and some of its tributaries, and from them we have received the little knowledge that we do possess of this immense tract of wild forest. It is the haunt of innumerable wild animals, especially monkeys and serpents, and of a few aboriginal inhabitants, who are sunk in the lowest stage of barbarism.

SILVER (symb. Ag., equiv. 108, sp. gr. 10·53) is a metal which, in its compact state, is of a brilliant white colour, possesses the metallic lustre to a remarkable degree, is capable of being highly polished, and evolves a clear ringing sound when struck. It is harder than gold, but softer than copper, and is one of the most ductile of the metals. It is malleable, may be hammered into very thin leaves, and may be drawn out into very fine wire, the thinnest silver-leaf having a thickness of only $\frac{1}{100000}$th of an inch, and one grain of the metal being capable of yielding 400 feet of wire. It possesses a high degree of tenacity, a wire with a diameter of $\frac{1}{12}$th of an inch being able to support a weight of nearly 188 pounds. It requires a heat of 1873° Fahr. to fuse it, and on cooling, expands at the moment of solidification. It is an excellent conductor of heat and electricity, and is not affected by exposure even to a moist atmosphere at any temperature. When, however, it is fused, it absorbs a considerable quantity of oxygen, which it expels in the act of solidification with a peculiar sound, technically known as *spitting*.* But although it does not rust or become oxidised, it usually becomes tarnished on prolonged exposure to the air, owing to the formation of a film of sulphide (or sulphuret) of silver, and this change occurs more rapidly in towns than in the country, in consequence of sulphuretted hydrogen being more abundant in the atmosphere of the former than of the latter. This metal is unaffected by the hydrates or nitrates of the alkalies, even at a high temperature, and hence silver crucibles, &c. are highly useful in many laboratory operations.

Hydrochloric and dilute sulphuric acid have scarcely any action on silver, but nitric acid and boiling sulphuric acid oxidise it, and form salts; nitric acid being by far its best solvent. Silver has strong affinities for chlorine, bromine, iodine, and sulphur, and combines with the first three and sulphuretted hydrogen at ordinary temperatures. It is well known that common salt, especially in the melted state, when left for any time in contact with silver, corrodes that metal, soda being formed from the oxygen of the air, while the liberated chlorine attacks the silver.

Silver is frequently met with in the native state, crystallised in cubes or octahedrons, or occurring in fibrous masses. It is also found in combination with gold, mercury, lead, antimony, arsenic, sulphur, &c., and sulphide of lead is almost always accompanied with a greater or less amount of sulphide of silver; it is, however, never found as an oxide.

Silver forms compounds with oxygen—viz., hemioxide, or argentous oxide, Ag_4O; protoxide, or argentic, Ag_2O; and peroxide, or argentic dioxide, Ag_2O_2. All these oxides are reduced by heat to the metallic state, and are very readily decomposed by the action of light. The protoxide, Ag_2O, is the only one of these compounds requiring special notice. It is a dark-brown heavy powder, devoid of taste or smell, somewhat soluble in water, to which it communicates a metallic taste and an alkaline reaction. It acts as a powerful base, neutralising the strongest acids, and forming normal salts with them. It is obtained by the addition of a solution of potash to a solution of the nitrate or any other soluble salt of silver, falling as a hydrated oxide, which, at a temperature above 140°, becomes anhydrous. If a concentrated solution of ammonia be digested for some hours upon freshly precipitated protoxide of silver, Fulminate of Silver (q. v.), or Fulminating Silver in the form of a black powder is produced, and the same dangerous compound is formed when an ammoniacal solution of nitrate of chloride of silver is precipitated by potash.

The salts which the protoxide of silver forms with acids are characterised by the readiness with which they decompose, the mere action of light blackening and partially reducing them. None of these salts occur in nature. The following are the most important of those which have been formed artificially.

* Although ordinary air has no oxidising action on silver, ozonised air rapidly attacks it.

Nitrate of Silver ($AgNO_3$) crystallises in large, colourless, transparent square tablets, which blacken on exposure to light, or in contact with organic matters, owing to reduction, and dissolve in their own weight of cold water. This property of producing a permanent black colour with organic matters has led to its employment as a *marking ink* * for linen, &c. The black stains which it forms on the skin, on linen, &c., may be removed by the employment of a strong solution of iodide of potassium, or more readily by a solution of cyanide of potassium. The crystals fuse at a temperature of about 425°, and the molten mass, when cast into cylindrical moulds, solidifies, and forms the sticks of *lunar caustic* which are employed in surgery, medicine, and Photography (q. v.). Nitrate of silver is prepared by dissolving pure silver in moderately strong nitric acid, and evaporating till the solution is sufficiently concentrated to crystallise. 'The most characteristic test for the salts of silver is the action of hydrochloric acid, or of a soluble chloride, which produces a white curdy precipitate of chloride of silver, insoluble in nitric acid, but readily soluble in ammonia; it is also soluble in hyposulphite of soda, with which it forms an intensely sweet solution; cyanide of potassium also dissolves it; the chloride of silver speedily assumes a violet tinge when exposed to light.'—Miller's *Elements of Chemistry*.

Of the haloid salts of silver, several occur native. The most important of these compounds is the *protochloride of silver* (AgCl), which is found native either in cubes or in a dense semi-transparent mass, and is known as *horn silver*, and may be procured as a dense white flocculent precipitate by the procedure described in the preceding paragraph. In consequence of its sensibility to light, it is employed in photography. When heated to about 500°, it fuses into a yellow fluid, which, on cooling, solidifies into a yellowish gray semi-transparent horny mass. This salt is insoluble in water and in all the diluted acids, but dissolves in a solution of ammonia, from which it crystallises in octahedra. Its solution in a solution of hyposulphite of soda is employed in silvering iron, copper, and brass goods. Traces of this salt are found in sea-water, the chloride of sodium probably acting as the solvent. *Bromide of silver* (AgBr) is found in Mexico, where it is known as *Plata verte*, or green silver, in the form of small crystals or crystalline granules of a pale olive-green tint. *Iodide of silver* (AgI) occurs native in several Mexican mines in the form of thin, flexible, pearly scales.

Sulphide (or *sulphuret*) *of silver* (Ag_2S) is the principal ore of silver. It occurs native, sometimes crystallised in cubes or octahedra, and sometimes in masses. From its gray metallic lustre, it has received from mineralogists the name of *silver glance*. It is well known that if silver spoons are allowed to remain in contact with boiled eggs for some time, they become tarnished by the action of the sulphur; a minute quantity of sulphuretted hydrogen being probably evolved. The discoloration is easily removed by washing the darkened silver with a solution of cyanide of potassium. Sulphide of silver unites with various other metallic sulphides when fused with them, especially with the sulphides of arsenic and antimony. *Red silver ore* ($3Ag_2S.Sb_2S_3$) is a native compound of this kind.

The alloys of silver and copper (see ALLOY and MINT), when cast into ingots, are usually found to differ in their composition in the internal and external parts, in consequence of a molecular change that takes place during the cooling and slow solidification of the molten mass. In bars containing more than 719 parts of silver in 1000, the central portions are richer in silver than the exterior; in alloys of less value, the reverse is observed, while in ingots containing 950 or more parts of silver in 1000, the composition is nearly uniform throughout. When exactly 719 parts of silver and 281 of copper are combined (corresponding to the formula Ag_3Cu_2), no separation whatever of the metals occurs. Many metals, as tin, zinc, antimony, bismuth, arsenic, &c., when mixed with silver, render it brittle and unfit for its ordinary uses; they are, however, easily removed in the process of refining. An alloy consisting of five parts of silver, six of brass, and two of zinc, is used as a solder for silver. An alloy of silver and mercury, known as *silver amalgam*, occurs native in a crystallised form. It is a mineral of a silvery white colour, and its composition is represented by the formula, $AgHg_2$.

Silver, like gold, has been known and prized from the earliest ages. Its production is not at all keeping pace with the new discoveries of gold. The richest silver mines in the world are those of Mexico, the estimated annual yield of which is about 1,600,000 lbs. troy of the pure metal. Peru is next in importance, but its produce is not more than a fifth or a sixth that of Mexico. Chili and Bolivia have also considerable silver mines. The total production of silver from all sources for 19 years (1849—1867, both inclusive) has been estimated at $933,000,000. That of the United States for the same time has been estimated by different authorities from $73,000,000 to $100,000,000. In 1860—1861 the silver regions of Nevada were discovered, and the annual product greatly increased; that of 1867 for that state alone having been $12,500,000; Idaho, $2,500,000; and Colorado, $500,000. The product of Nevada declined greatly in 1869.

Of European countries, Spain is the most productive in silver. In the district of Guadalaxara, some new mines were opened a few years ago, which have already reached a degree of prosperity quite extraordinary, the vein upon which they are placed containing, curiously enough, large quantities of a silver ore, called freislebenite (a compound of sulphur, antimony, lead, and silver), which has been hitherto looked upon as a very rare natural substance. Next to Spain, Austria, Saxony, and the Hartz district in Northern Germany, yield the largest supplies. The silver mines of Kongsberg in Norway are likewise valuable, and have been long famous. Great Britain has no silver mines, properly so called, of any extent; but since the introduction in 1829 of Pattinson's process for the desilverising of lead smelted from argentiferous galena, a large quantity has been annually obtained in this way, the produce in 1864 being 641,088 ounces. (See LEAD.) In the mineral veins of Cornwall, some bunches of true silver ores have recently been found, but of limited extent.

The forms in which silver is found in nature are numerous, but we need only notice a few of them. It is frequently found native in crystallised and amorphous masses, which are sometimes of considerable size. One fine piece found at Kongsberg is

* Brande gives the following directions for preparing marking ink: Dissolve two drachms of nitrate of silver and one drachm of gum-arabic in seven drachms of water, and colour the liquid with Indian ink. The cloth must be first prepared by moistening the spot with a few drops of a soda solution, prepared by dissolving two ounces of crystallised carbonate of soda and two drachms of gum in four ounces of water. Professor Miller recommends, as a cheap indelible marking ink, a solution of coal-tar in naphtha; it resists the action of chlorine, and is used by bleachers to mark their goods.

now in the Copenhagen Museum, and weighs 500 lbs. But the quantity of silver found in nature in the metallic state is comparatively small. Its principal ores are the different sulphurets—viz., silver glance, or sulphuret of silver, containing when pure 87 parts of silver and 13 of sulphur; brittle silver ore, or sulphuret of silver and antimony, of which the composition is, silver 68·5, antimony 14·7, and sulphur 16·4; and red silver ore, called also ruby silver, of which there are a dark and a light kind, the composition of the former being similar to brittle silver ore, but it is a little less rich in silver, and the latter only differs in containing arsenic instead of antimony. The bulk of the silver obtained in Mexico and South America is got from these ores. The only other of much importance, except the mixed ores to be presently noticed, is horn silver, or chloride of silver. In a pure state, it consists of silver 75, and chlorine 25. It occurs extensively in Mexico and Peru, but is not common in European mines.

Besides the ores named above, a good deal of the silver of commerce is obtained from mixed ores, that is, the ores of other metals are frequently found to contain it. In many cases, the amount of silver falls greatly short of 1 per cent. These ores are for the most part sulphurets of tin, arsenic, copper, iron, and lead.

In the reduction of silver ores, the processes followed are based upon the fact, that both lead and mercury have a strong affinity for silver. A more recent process depends upon the solubility of chloride of silver in a hot solution of common salt, and its separation again on cooling.

The simplest process is ordinary smelting, and is only applied to the richest ores. These are crushed, mixed with old slag, lead in some form, and a little iron ore and lime. The mixture is then heated in a furnace with charcoal, which brings down the silver and lead together as an alloy. The silver is afterwards easily separated by cupellation, the principle of which is described in the article ASSAY; but on the large scale, instead of a small bone ash cupel, a cupellation furnace, say 6 feet in diameter, is used, of which fig. 1 is a section. Here

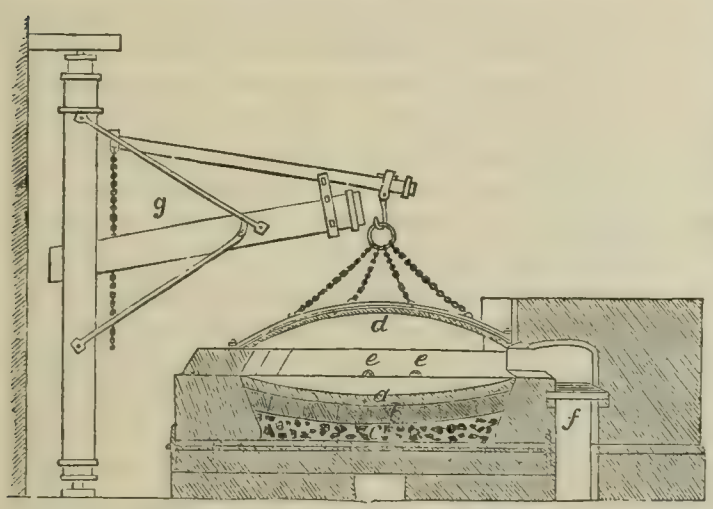


Fig. 1.—Silver Cupellation Furnace.

the alloy is melted, bellows are used to remove the lead as litharge, or oxide of lead, and a cake of silver is left on the cupel forming the bottom of the furnace.

It happens that not many even of the richer ores are pure enough to be treated with advantage by simply roasting them with lead; accordingly, another plan, called the amalgamation process, is more commonly adopted. The following is an outline of the way in which this is practised at Freiberg in Saxony. Ore consisting chiefly of silica, with but little lead, copper, &c. as sulphurets, and only from 3 to 3½ oz. of silver per cwt., is ground to powder by machinery, described under METALLURGY; but a large proportion of sulphuret of iron is also present, or must be added. About 10 per cent. of common salt is then mixed with the ore, and the mixture heated in a

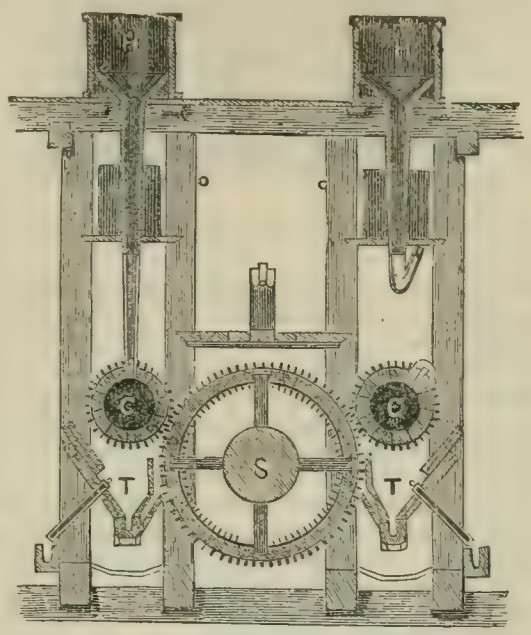

Fig. 2.—Vertical Section of Amalgamating Apparatus.

CC, oak barrels; S, toothed wheel for setting barrels in motion; H, hoppers with hose for passing the mixed ore into the barrels; TT, troughs for the reception of the charge when the amalgamation is complete.

Reverberatory Furnace (q. v.) to a temperature sufficient to expel water, and in part arsenic, zinc, and antimony. After two hours, the sulphur of the sulphurets takes fire, and is burned off as sulphurous acid, or converted into sulphuric acid, so that the metals become oxides and sulphates. The temperature of the furnace is now raised, when the chlorine of the common salt forms volatile chlorides with zinc, antimony, and iron, and a fixed chloride with silver. During the roasting, the contents of the furnace are continually stirred, so that they ultimately form a coarse powder.

The product of the roasting furnace, after being ground to a fine powder, is mixed in the proportion of 10 cwt. with 3 cwt. of water and 1 cwt. of iron in fragments; the mixture being effected in oak casks made to revolve on their axes. See figs. 2 and 3. This operation lasts two hours, and effects the solution of the sulphates and common salt; and the reduction of the chloride of iron and the chloride of copper to subchlorides—a change required in order to prevent the formation of subchloride of mercury in the next stage, which would be lost, and so cause a waste of quicksilver. Next follows the principal part of the process, the mercurialising. Quicksilver to the amount of 20 cwt. is made to run into each of the casks, which are then set in motion, and continue for 22 hours at the rate of 12 revolutions per minute. The result of this is the reduction of the chloride of silver in presence of the metallic mercury, with which the silver forms an amalgam.

In order to separate the amalgam from the earthy

matters and the sulphates and chlorides, the barrels, which were hitherto only two-thirds full, are now filled with water (the dilution throwing down any chloride of silver held in solution by the sea-salt), and kept revolving for two hours; after which, by

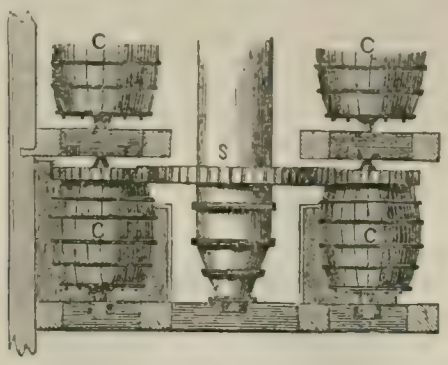

Fig. 3.—Plan of Part of Amalgamating Apparatus.

means of a stop-cock, the amalgam is allowed to flow into the amalgam chamber, and the rest of the contents, except the iron fragments, into a wash-tun. The superfluous quicksilver has next to be separated from the amalgam. This is done in bags of ticking, through which the mercury at first flows readily by its own weight, and is afterwards squeezed out on a flat surface. The result of this operation is, that the amalgam of mercury, silver, copper, &c. is left in the bags: its actual composition being nearly 85 per cent. of mercury, 10 per cent. of silver, and 5 of copper, lead, and antimony. Finally, the quicksilver of the amalgam itself is separated by heat in the distilling furnace, fig. 4. Here the

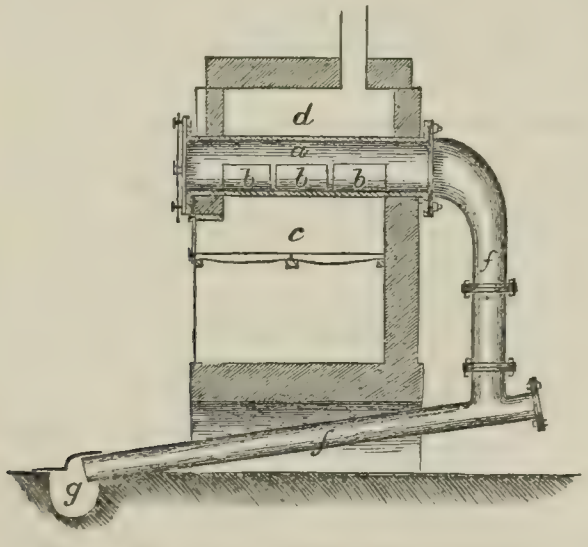

Fig. 4.—Furnace for Distilling the Amalgam.
a, iron retort; *b*, iron pots; *c*, fireplace; *d*, flue; *f*, condensing pipe; *g*, trough for collecting mercury.

amalgam is put into a row of iron pots, which go into a large retort. When heat is applied, the quicksilver volatilises, and is condensed in a pipe attached to the retort, from which it is collected in a trough. The impure silver left in the retort is refined by fusion and subsequent cupellation.

There is another process carried on at Freiberg and elsewhere, by which the use of mercury is dispensed with. It consists in treating the ore as above described till it leaves the roasting-furnace. At this stage, the roasted ore is digested in a warm concentrated solution of sea-salt, which readily dissolves the chloride of silver. On diluting the solution, and allowing it to cool, the chloride of silver will separate again, and could thus be obtained as a compound of comparative purity. But it is found preferable, instead of diluting the liquid, to introduce metallic copper, which has the property of decomposing the chloride of silver: the chlorine unites with the copper to form chloride of copper, and the silver is precipitated.

In the mining regions of the United States several processes are employed, the product of foreign science directed by actual experience in this country. These are the cylinders of Brückner, and the shaft-furnace of Stetefeldt, both American inventions, by which amalgamation is conducted more economically than elsewhere. See *Statistics of Mines and Mining*, by R. W. Raymond, Washington, 1870.

It has now become a common practice at Swansea, where the great British copper smelting-works are situated, to extract the silver which exists in an appreciable, though small quantity, in many copper ores. Several processes are followed, but it will suffice to name the liquation process. Blister-copper, that is, copper unrefined, which has been smelted from an argentiferous ore, is melted with three or four times its weight of lead, and cast into ingots. When these are moderately heated, the copper does not fuse, but the lead and silver melt, and run off together. The lead is then separated from the silver in the usual way by cupellation.

The physical and chemical properties of silver are such as make it specially valuable for many purposes in the arts; the chief of which are noticed in the articles Alloy, Mint, Plating, Galvanism, and Photography. Ordinary mirrors have their *silvering* produced by a coating of an amalgam of tin and mercury; but a process has for some years been practised, by which a mirror-like coating of silver is given to glass objects of any round as well as flat form. It consists in mixing some of the salts of silver, usually the nitrate, with an alcoholic solution of grape-sugar or of certain essential oils, which has the property of reducing the silver to the metallic state, and depositing it on the surface of the glass.

Medicinal uses of Silver. *Nitrate of silver*, in small doses, constitutes an excellent tonic, and it appears to exert almost a specific influence over certain convulsive diseases. As a tonic, it is frequently prescribed in the early stages of phthisis, and in cases of irritability of the mucous membrane of the stomach; and epilepsy and chorea frequently yield to its influence, when many other remedies have been tried in vain. There is unfortunately one great drawback to its administration—viz., that when its use has been continued for some time, this salt communicates a permanent slate-like or bluish-gray hue to the skin. There is very little danger of this change of colour occurring, if the medicine is not administered for a longer period than three months. In prescribing this salt, it is usual to begin with a small dose, about one-sixth of a grain, and gradually to increase it to two or three grains, three times a day. It is best administered in pills made with some vegetable extract. The surgical uses of nitrate of silver have been already noticed in the article on Lunar Caustic.

Oxide of silver is employed in the same cases as the nitrate. It is especially recommended in chronic affections of the stomach, and in menorrhagia. It may be given in the same doses as nitrate. *Chloride of silver* has been employed both in America and in Germany in the same cases as the nitrate, and in certain forms of syphilitic disease. It is stated not to produce the discoloration of the skin caused by the nitrate; but as the same statement was confidently made regarding the oxide, and was found to be fallacious, we are not inclined to put any faith in this assertion, especially as the nitrate must

at once converted into a chloride by the free hydrochloric acid of the gastric juice.

SILVERING GLASS. See MIRROR.

SIMARUBA'CEÆ, a natural order of exogenous plants, consisting of trees and shrubs; with alternate, generally compound leaves, without stipules; regular, generally hermaphrodite flowers. The species are not numerous; they are found in the tropical parts of Asia, Africa, and America. The whole order is characterised by great bitterness. Quassia (q. v.) and Bitterwood (q. v.) belong to it. The seeds of *Simaba cedron*, a small tree found in the Isthmus of Darien and neighbouring countries, are known by the name of *Cedron*, are intensely bitter, and are greatly esteemed in Central America and New Granada as a cure for intermittents, dyspepsia, and other diseases.—SIMARUBA BARK, employed as a tonic in dyspepsia, dysentery, &c., is the bark of the roots of *Simaruba amara*, a native of the West Indies, called *Mountain Damson* in Jamaica. It was first brought to Europe in 1713.

SIMBI'RSK, a government of Russia, bounded on the E. by the Volga, and on the W. by the governments of Nijni-Novgorod and Penza. Area, 18,778 sq. m.; pop. 1,183,312. The surface is for the most part level, and the soil of remarkable fertility, and there are excellent and extensive meadows and pasture-grounds. The fisheries and the commerce on the Volga, and cattle-breeding, are important.

SIMBIRSK, capital of the Russian government of the same name, on the right bank of the Volga, 220 miles south-east of Nijni-Novgorod. Leather, soap, and candles are manufactured, considerable trade is carried on by the Volga, and there is a famous annual fair. During the years 1864 and 1865, S. suffered severely from fires. Pop. 19,000.

SIMEON, REV. CHARLES, an eminent evangelical preacher of the English Church, was born at Reading in Berkshire, September 24, 1758. Educated at Eton and Cambridge, he was ordained a priest in 1782. His first religious impressions occurred during his residence at the university, and produced a permanent change in his character. From being a somewhat vain and dressy young gentleman, he passed into an ardent and zealous preacher of the Cross, and this he remained during the fifty-four years of his public ministry. His career was not marked by many incidents. Appointed vicar of Trinity Church, Cambridge, in the year of his ordination, and vice-provost of his own college (King's) in 1790, he continued to hold these offices to the close of his life, November 13, 1836. As a preacher S. was distinguished for an impassioned evangelicalism in language, sentiment, and doctrine, that at first roused against him a bitter and protracted opposition. His earnestness, however, met with its due reward. Friends and followers sprung up; and in course of time, S. became a centre of evangelical influence, that began to spread itself over the whole church, and gave birth to its great missionary activity in recent years. S. may even be regarded as the founder of the 'Low-church' party, and on the whole, fairly represents their earnestness, dogmatism, mediocre intellect, and limited scholarship. For an account of S.'s life and labours, see *Memoirs of the Rev. Charles Simeon*, by the Rev. W. Carus (Lond. 1857). S.'s *Horæ Homileticæ* (21 vols., 1832) are very popular among sermon-readers and sermon-makers of evangelical tendencies.

SI'MEON STYLI'TÉS. See PILLAR-SAINTS.

SIMFERO'POL, a town of Russia, in the Crimea, capital of the government of Taurida, stands on the Salghir, 45 miles north-east of Sebastopol. The valley of the river is studded with charming villas, and the town is surrounded by gardens, and has a picturesque appearance. The older part comprises the old Tartar town of Ak-Metchet, or White Mosque—the new part, containing the government buildings, is very handsome. Fruits are largely grown in the vicinity, and exported. Pop. 16,849.

SI'MIA AND SIMI'ADÆ. See MONKEY.

SIMILAR FIGURES, in Geometry, are figures which exactly correspond in shape, but may or may not be of the same size. If the figures be rectilineal, then the criterion of similarity is that every pair of corresponding sides should have the same ratio to each other, and that each angle of the one figure should be equal to a corresponding angle of the other. If the figures be triangular, the proportionality of the sides carries with it the equality of the angles, and *vice versâ*, but only in this case. *Similar segments* of circles are those in which, and on whose bases, similar triangles can be inscribed; or, as it is otherwise expressed, those which contain equal angles—a satisfactory test that they are each the same part of their respective circles. *Similar solids* are those which are bounded by similar planes similarly situated to each other. All similar plane figures are to one another as the squares of any corresponding sides, and all similar solids are as the cubes of their corresponding sides. Thus, a circle which has 3 (3 : 1) times the diameter of another, has 9 ($3^2 : 1^2$) times its area, and a globe which has 3 (3 : 1) times the diameter of another has 27 ($3^3 : 1^3$) times the volume.

SI'MLA, a British sanatorium, in the north-west of India, about 170 miles in direct line north of Delhi. It consists of a number of houses irregularly scattered over a mountain-ridge, with a noble panorama expanding on all sides of it. European fruits and vegetables are successfully and extensively cultivated, and the climate is salubrious. The pop., which is very fluctuating, is said to range from 2000 to 20,000.

SIMO'DA (Lowland), a harbour of Japan, at the southern extremity of Cape Idzu, and about 80 miles from Yeddo, opened to foreign commerce by the Dutch treaty of 1857. The streets of the town are about 20 feet wide, and at right angles. The pop. is estimated at 80,000. In 1854, the town was nearly destroyed by an earthquake, while the harbour was so scoured out that hardly any holding-ground was left for ships on the granite bottom.

SIMON, RICHARD, a distinguished orientalist and critical scholar, was born at Dieppe, May 13, 1638. Having completed his studies, he entered the Congregation of the Oratory in 1659, but soon afterwards withdrew. He returned, however, in the latter part of 1662. For a time, he delivered lectures on Philosophy in the college of Juilly; but his studies eventually turned upon theology, oriental languages, and biblical criticism. At one time, he thought of entering the Jesuit order, but he remained in the Oratory; and it was while still a member of that congregation that he published his well-known work on the doctrine of the oriental church regarding the Eucharist, designed as a supplement to the celebrated *Defence of the Perpetuity of the Faith in the Blessed Eucharist*, by Arnauld and Nicole, but criticising that work very severely. This and other controversies to which his later writings gave rise, led to his again withdrawing from the Oratory in 1678. In that year he retired to Belleville, as curé; but in 1682, he resigned his parish, and lived in literary retirement, first at Dieppe, and afterwards in Paris. His health having given way, he returned once again to his native place,

Dieppe, where he died in April, 1712. Few writers of his age played so prominent a part in the world of letters, and especially in its polemics. There is hardly a critical or theological scholar among his contemporaries with whom he did not break a lance—Spanheim, Le Clerc, Du Pin, Jurieu, and Jurieu's great antagonist, Bossuet. The principal work of S. is his *Histoire Critique du Vieux Testament* (Paris, 1678), in which he anticipates the most important conclusions of all the later rationalistic scholars of Germany, and also their method of investigation. For example, he conceives himself to have disproved the Mosaic authorship of the Pentateuch, and assigns its composition to the scribes of the time of Ezra. Other writings of S.'s are *Histoire Critique du Texte du Nouveau Testament* (Rotterd. 1689); *Disquisitiones Criticæ de variis Bibliorum Editionibus* (1684); *De l'Inspiration des Livres Sacrés* (Rotterd. 1687); and *L'Histoire Critique des Principaux Commentateurs du Nouveau Testament* (Rotterd. 1692), in which he assails the theology of the Fathers, and particularly that of Augustine, as a departure from the simple and less rigid doctrines of the primitive church. Among the Fathers, his most esteemed authority was Chrysostom. Bossuet replied to this last work by his *Defense de la Tradition et des Saints Pères.* S. frequently published under assumed names—as his *Dissertation Critique* on Dupin's *Library of Ecclesiastical Writers*, under the name of Jean Reuchlin; a work, *Histoire Critique sur la Créance et des Coutumes des Nations du Levant*, under the anagram of Monis; and a *Histoire de l'Origine et du Progrès des Revenus Ecclésiastiques* under the name of Jerome Acosta. No collected edition of his works has ever appeared; in the natural progress of the science of criticism, the most famous of them have lost most of their prestige, and are displaced by recent, and often second-hand compilations upon the subjects, which, in the days of S., were comparatively new and unexplored; but still there is much to be learned even from such of his works as have been forgotten by ordinary students.

SIMO'NIDÉS, a celebrated Greek lyric poet, was born at Iulis, in the island of Ceos, in the year 556 B.C., and educated probably with a view to making music and poetry a profession. He left his native island on the invitation of Hipparchus, who, by means of great rewards, induced him to reside at Athens, where also lived at that time Anacreon and Lasus, the teacher of Pindar, although no intimacy seems to have sprung up between S. and his two rivals. It was probably after the expulsion of Hippias (510 B.C.) that he took up his residence in Thessaly, under the patronage of the Aleuads and Scopads, who appear to have treated him in a very niggardly fashion. Shortly before the invasion of Greece by the Persians, he returned to Athens, and employed his poetic powers in the composition of elegies, epigrams, dirges, &c., in connection with that momentous struggle, taking the prize, in regard to the battle of Marathon, out of the hands of his rival Æschylus. In the year 477 B.C., when S. was 80 years of age, he came off victor for the 56th time in a poetical contest at Athens. Shortly after this, he went to reside at the court of Hiero of Syracuse, where he died in 467 B.C., at the age of 90. S. appears to have scandalised his contemporaries by writing for hire; and Pindar, his great rival, accuses him, apparently not without good reason, of excessive avarice. His poetry is imbued with a comparatively high morality. He brought to perfection the elegy and epigram, and excelled in the dithyramb and triumphal ode; he seems also to have completed the Greek alphabet by the addition of the double letters and long vowels, and to have invented the art of artificial memory. The characteristics of his poetry are sweetness, polish combined with simplicity, genuine pathos, and great power of expression, although in originality he is much inferior to his contemporary Pindar. The best edition of his fragments is that of Schneidewin, entitled *Simonidis Cei Carminum Reliquiæ* (Brunswick, 1835).

This S. must be carefully distinguished from the iambic poet SIMONIDES of Amorgos, who flourished about 100 years previous to S. of Ceos.

SIMONOSE'KI, a town of Japan, in 33° 56′ N. lat., and 131° E. long., at the south-west extremity of the island of Nipon, and at the entrance of the inland sea Suonada. It is surrounded by hills, and consists of one main street, containing about 10,000 inhabitants. The warehouses—the principal buildings—are built of mud and wood, coated with cement, and are said to be fireproof. S. is a depôt for receiving the European imports from Nagasaki, to be sent into the interior of the country; also for the produce from Osaca, which is reshipped to Nagasaki and other places.

SI'MONY, in English Law, is the corrupt presentation of any one to an ecclesiastical benefice for gift-money or reward, and is so called from its resemblance to the sin of Simon Magus. In the canon law, it was considered a heinous crime, and a kind of heresy. As the canonical punishment, however, was not deemed sufficient, a statute was passed in the time of Elizabeth, defining its punishment. A simoniacal presentation was declared to be utterly void, and the person giving or taking the gift or reward forfeited double the value of one year's profit; and the person accepting the benefice was disabled from ever holding the same benefice. Presentation bonds, however, taken by a patron from a presentee to resign the benefice at a future period in favour of some one to be named by the patron, are not illegal, provided the nominee is either by blood or marriage an uncle, son, grandson, brother, nephew, or grandnephew of the patron, and provided the bond is registered for public inspection in the diocese. The result of the statutes is that it is not simony for a layman or spiritual person, not purchasing for himself, to purchase while the church is full, either an advowson or next presentation, however immediate may be the prospect of a vacancy, unless that vacancy is to be occasioned by some agreement or arrangement between the parties. Nor is it simony for a spiritual person to purchase for himself an advowson, although under similar circumstances. It is, however, simony for any person to purchase the next presentation while the church is vacant; and it is simony for a spiritual person to purchase for himself the next presentation, although the church be full.

SIMOO'M (otherwise written Simoun, Semoun, Samoun, Samūn), or Sambuli, a name derived from the Arabic *samma*, signifying hot, poisonous, or generally whatever is disagreeable or dangerous, and applied to the hot suffocating winds which are peculiar to the hot sandy deserts of Africa and Western Asia. In Egypt, it is called *khamsin* (Ar., fifty) because it generally continues to blow for 50 days, from the end of April to the time of the inundation of the Nile.

Owing to the great power of the sun's rays, the extreme dryness of the air, and the small conducting power of sand causing the accumulation of heat on the surface, the superficial layers of sand in the deserts of Africa and Arabia often become heated to 200° F. to a depth of several inches. The air resting on this hot sand becomes also highly heated,

thus giving rise to ascending currents; air consequently flows towards these heated places from all sides, and these different currents meeting, cyclones or whirling masses of air are formed, which are swept onward by the wind prevailing at the time. Since the temperature, originally high, is still further raised by the heated grains of sand with which the air is loaded, it rapidly increases to a degree almost intolerable. In the shade, it was observed by Burckhardt in 1813 to have risen to 122°; and by the British Embassy to Abyssinia in 1841 to 126°. It is to the parching dryness of this wind, its glowing heat (about 200°), and its choking dust, and not to any poisonous qualities it possesses, that its destructive effects on animal life are to be ascribed.

The approach of the Simoom is first indicated by a thin haze along the horizon, which rapidly becomes denser, and quickly overspreads the whole sky. Fierce gusts of wind follow, accompanied with clouds of red and burning sand, which often present the appearance of huge columns of dust whirling forward; and vast mounds of sand are transported from place to place by the terrible energy of the tempest. By these mounds of sand, large caravans are frequently destroyed; and even great armies have been overwhelmed by them, as in the case of Cambyses, who was overtaken by the Simoom on his march through the desert to pillage the temple of Jupiter Ammon, and perished with 50,000 of his troops. The destruction of Sennacherib's army is supposed to have been caused by the Simoom. The Simoom generally lasts from 6 to 12 hours, but sometimes for a longer period.

The effects of this wind are felt in neighbouring regions, where it is known under different names, and it is subject to important modifications by the nature of the earth's surface over which it passes. In Italy, it is called the *Sirocco*, which blows occasionally over Sicily, South Italy, and adjoining districts. It is a hot moist wind, receiving its heat from the Sahara, and acquiring its moisture in its passage northward over the Mediterranean. It is the plague of the Two Sicilies, and while it lasts a haze obscures the atmosphere, and so great is the fatigue which it occasions that the streets of Palermo become quite deserted. The Sirocco sometimes extends to the shores of the Black and Caspian Seas, and under its blighting touch, sheep and cattle die in the steppes beyond the Volga, and vegetation is withered and dried up. It is called the *Samiel* in Turkey, from its reputed poisonous qualities.—The *Solano* of Spain is a south-east wind, extremely hot, and loaded with fine dust, which prevails at certain seasons in the plains of Mancha and Andalusia, particularly at Seville and Cadiz. It produces giddiness, and heats the blood to an unusual degree, causing general uneasiness and irritation; hence, the Spanish proverb: 'Ask no favour during the Solano.'—The Harmattan (q. v.) of Guinea and Senegambia belongs to the same class of winds.

SIMPLE CONTRACT, in English law, means any contract which is constituted by word of mouth or by a writing not under seal. See CONTRACT.

SI'MPLON (Ital. *Sempione*), a famous mountain of Switzerland, one of the Lepontine Alps, in the east of the canton of Valais, and near the Piedmontese frontier, rises to the height of 11,124 feet. The *Simplon Road*, one of the greatest engineering achievements of modern times, leads over a shoulder of the mountain from which it derives its name (the *Pass of the Simplon*, 6592 feet) from Brieg in Valais to Domo d'Ossolo in the north of Piedmont. The road was commenced in 1800 under the direction of Napoleon, and was completed in 1806. It is from 25 to 30 feet broad, and has nowhere a slope greater than 1 in 13. It is carried across 611 bridges, over numerous galleries cut out of the natural rock, or built of solid masonry, and through great tunnels. Close to the highest point is the *New Hospice*, one of the 20 edifices on this route for the shelter of travellers. It was greatly damaged by storms in the years 1834, 1839, and 1850.

SIMROCK, KARL, a German poet and scholar, who has done more perhaps than any other man to make his countrymen familiar with their early literature, was born at Bonn, 28th August 1802. He studied at the university of his native city and afterwards at Berlin, and in 1823 entered the Prussian state service. His first work was a translation into Modern German of the *Nibelungenlied* (Berl. 1827; 9th ed. Stuttg. and Tüb. 1854), followed by a translation of the songs admitted by Lachmann to be genuine, under the title *Zwanzig Lieder von den Nibelungen* (Bonn, 1840). Soon after the publication of his translation of Hartmann von der Aue's *Armer Heinrich* (Berl. 1830), he was compelled to leave the Prussian service on account of a revolutionary poem which he wrote. Since then he has devoted himself exclusively to literature, and more particularly to the early literature of his own country, which he has modernised in splendid style. In 1850, he was appointed professor of German Language and Literature at Bonn, a situation which he still holds. His principal works, besides those already mentioned, are: *Quellen des Shakspeare in Novellen, Märchen, und Sagen* ('Sources of Shakspeare in Novels, Tales, and Legends,' 3 vols. Berl. 1831), executed in conjunction with Echtermeyer and Henschel, but of which the most important part was S.'s; *Novellenschatz der Italiener* (Berl. 1832); a translation, with commentary, of the poems of Walther von der Vogelweide (2 vols. Berl. 1833) in conjunction with Wackernagel; and of *Wieland der Schmied. Deutsch Heldensage* (Bonn, 1835), one of the freshest of the German medieval epics; *Rheinsagen aus dem Munde des Volkes und Deutscher Dichter, fur Schule, Haus, und Wanderschaft* ('Legends of the Rhine, from the mouth of the people and German poets, for School, Home, and Travelling,' 4th ed. Bonn, 1850, latest ed. 1857); a collection of German *Volksbücher* ('People's Books'), of which 36 had appeared by the year 1854, and which are still going on, comprising national proverbs, songs, and riddles, besides a vast quantity of stories; a translation of Wolfram von Eschenbach's *Parzival und Titurel* (Stuttg. and Tüb. 1842); and *Das Helden buch*, partly translations and partly original poems (1843—1849), illustrative of the heroic traditions of the Teutonic race. A separate collection of his own poems (*Gedichte*) was published at Leipzig (1844, new ed. 1863). Later productions are a translation of the Songs of the Edda (Stuttg. and Tüb. 1851, 3d ed. 1863). A *Handbuch der Deutschen Mythologie* (2 vols. Bonn, 1853—1855, 2d ed. 1864), and an *Altdeutsches Lesebuch in Neudeutscher Sprache* (Stuttg. and Tüb. 1854); *Das Deutsche Kinderbuch, Reime, Lieder, &c.* (1856—1857); *Der Wartburg Krieg, herausgegeben, geordnet, ubersetzt, und erläutert* (1858); *Die Nibelungenstrophe und ihr Ursprung; Beitrag zur Deutschen Metrik* (1858); *Lieder vom Deutschen Vaterlande* (1863); *Deutsche Märchen* (1864).

SIMSON, ROBERT, a celebrated Scotch mathematician, was born at Kirton Hall in Ayrshire, October 1687. He was educated at the university of Glasgow with a view to the clerical profession, and attained great eminence in classical and mathematical knowledge. His taste for mathematics gradually gained the ascendency, and all other

pursuits were abandoned. After a brief residence in London, during which he made the acquaintance of Dr Halley, Mr Ditton, and others, he returned to Glasgow, where in 1711 he was appointed Professor of Mathematics, and for 50 years discharged his professorial duties. S.'s reputation rests chiefly on his 'restorations,' or, as they might more properly be called, 'reconstructions,' of the Greek geometers. Some good judges are of opinion that he has corrected many errors in the original text, though his respect for the Greek mathematicians always led him to refer these to the ignorance of editors, and the negligence of copyists. His first attempt in this direction was to discover the signification of Euclid's porisms, the only datum being a most obscure and tantalising description of them by Pappus, the indefiniteness of which had foiled both Fermat and Halley. In this difficult task, S., however, succeeded; and a similar attempt, attended with similar success, on the 'loci plani' and the 'sectio determinata' of Apollonius, stamped him as one of the most elegant geometers of modern times. With the thorough insight which he had thus obtained into the nature and processes of the Greek analysis, he set himself to the correction of Euclid's *Elements*. This last work was published in 1758, and has deservedly enjoyed a high character; it has been frequently re-edited and republished as a school-book, especially the edition by Playfair. S. also published along with his edition of 'Euclid,' a list of Euclid's 'Data,' of which he subsequently issued a second edition; but of his other works, some of which were almost ready for publication, none were printed till after his death. He retired from his professorship in 1761, and employed himself chiefly in the correction of his various works till his death, October 1, 1768. Eight years after S.'s death, Earl Stanhope caused to be published (for private circulation) at his own expense, the work on Porisms, the two restored works of Apollonius, a posthumous tract on Ratios, and another on Logarithms; and an edition of Pappus, which was discovered after S.'s death, was presented to the university of Oxford.

SIN is the name given by theologians to the evil of human nature, to the moral defect or perversion which appears an inherent quality of the human will, and in a greater or less degree unavoidably characterises it in this life. It is something more than evil as affirmed of the external world or of the lower creation. *Evil*, as denoting decay or corruption in nature, is admittedly a mere relative term, for in truth decay is just as normal a process of creation as renovation, and corruption is the condition of restored health and beauty. In a similar manner, evil such as it exists in the lower animal creation, in the form of *prey* and in the forms of pain, of sickness, and of death—whatever be the special view taken of such phenomena—is never reckoned evil in the sense of *Sin*. In order to constitute the special idea of sin, it is always necessary to suppose a moral element in the evil to which it is applied. Whatever form of evil is independent of the human will as its source, origin, or agent, is not sin. Theologians, indeed, speak of original sin, or the sin of human nature, as distinguished from actual sin, or the particular transgression of the individuals composing mankind. According to a common theological view, men are not only sinners individually, but they are partakers of a sinful nature, with which their will has had nothing to do—with reference to which they have had no choice of good or evil. The evil has come to them by natural descent from the original parents of the race. But even the most extreme view of original sin preserves a hypothetical relation between every individual will and the primal transgression which it considers to be sin, not merely in those who committed it, but in those who have descended from them. All mankind are supposed to have been in Adam, the first sinner, as their representative, so that 'they sinned in him and fell with him in his first transgression.' Without such a hypothesis of unity between Adam and his race, so that his will was in some measure the typical or representative will of the race, the notion of original sin could not be maintained. For the relation between sin and will as a moral power, having the choice of good and evil, is a cardinal relation without which it would seem impossible to distinguish sin as a quality from other forms of evil in the world.

SI'NAI, the mount on which, according to the Pentateuch, God announced to Moses the ten commandments and the other laws by which the Israelites were to be bound. Its exact position is matter of dispute among travellers, but it is to be sought for in the mass of granite and porphyry mountains occupying the greater part of the Arabian peninsula, lying between the Gulf of Suez and Akabah, and rising to a height of 8000 or 9000 feet above the sea. This mountain-mass is divisible into three groups: a north-western, reaching, in Mount Serbal, an elevation of 6340 feet; an eastern and central, attaining, in Jebel Katherin, a height of 8160 feet; and a south-eastern, whose highest peak, Um Shaumer, is the culminating point of the whole Sinaitic range. Serbal, with its five peaks, looks the most magnificent mountain in the peninsula, and is identified with S. by the earlier Church Fathers, Eusebius, Jerome, Cosmas, &c.; but it does not meet the requirements of the Hebrew narrative, and even as early as the time of Justinian, the opinion that Serbal was the S. of Moses had been abandoned, and to a ridge of the second or eastern range that honour had been transferred, the northern summit of which is termed Horeb; and the southern, Jebel-Mûsa, or Mount of Moses, continues to be regarded by the great majority of scholars as the true Sinai. Its height is variously estimated at from 6800 to 7100 feet above the sea. At the eastern base of Jebel-Mûsa, in the ravine of Shouaib, stands in solitary peace the famous monastery of Mount S. The Sinaitic valleys abound in inscriptions, many of which have been deciphered, and are regarded as merely proper names inscribed by passing pilgrims or merchants, neither Jewish nor Christian.

SINCLAIR, THE FAMILY OF. The Scottish historical House of Sinclair or St Clair is of Norman descent, the surname (Latinised *De Sancto Claro*) being doubtless derived from possessions in Normandy. Two families bearing this surname, whose connection cannot now be traced, the St Clairs of Rosslyn and of Herdmanston, appear in Mid-Lothian and East Lothian in the beginning of the 12th century. Henry St Clair, *Vicecomes* of Richard Morville, Chancellor of Scotland, obtained, in 1162, a charter of the lands of Herdmanston, which have ever since continued in the family. His descendant rendered signal service to Robert Bruce, for which he is said to have presented him with a sword, still in the possession of the family, with the words inscribed: 'Le roy me donne, St Clair me porte.' The ancestor of the other line was William St Clair, who had Rosslyn confirmed to him by charter from David I. His descendant was, like his contemporary of the Herdmanston line, a companion-in-arms of Robert I., on whose death Sir William St Clair of Rosslyn was one of the knights selected to accompany the good Sir James Douglas, with the heart of his sovereign, to Jerusalem. With the Douglas, he fell in battle against the Moors in 1330

But the fortunes and importance of the family were principally due to the marriage of the son of this Sir William with the daughter of Malise, Earl of Strathearn, Caithness, and Orkney, and heiress of the Norwegian Jarls of the Orkneys. In this way the St Clair family acquired the Earldom of Orkney, coupled with some very stringent conditions of fealty to the king of Norway, which would have rendered it impossible for him, in the event of a war between the countries, to have retained both his Scotch and his Norse possessions. The Orkney earldom was, however, acknowledged and confirmed to him by Robert II.; and for the next two generations the power of the family continued to be little less than princely, the St Clair influence being further increased by intermarriages with near relatives of the royal house of Scotland. William, the third Earl, held the high offices of Lord Admiral, Lord Justice-general, Lord Chancellor, and Lord Warden of the three Marches. He was made Earl of Caithness in 1450. At his castle of Rosslyn he kept up an almost regal state and pomp. He founded and endowed a collegiate church there, bringing skilled workmen from foreign parts to build that rich and elaborate chapel, which is still among the architectural gems of Scotland, and in its style more resembles the churches of Spain than those of North Britain. His daughter was given in marriage to Alexander, Duke of Albany, son of James II. On the marriage of James III. with Princess Margaret of Denmark, the sovereignty of the Orkneys was made over by King Christiern in mortgage to the Scottish crown, a transaction which eventually led to the permanent cession of these islands. The earl soon after resigned into James's hands his earldom of Orkney, with the islands of Orkney and Shetland, and as a compensation—it has been said, a very inadequate one—obtained the lands of Dysart and Ravensheugh, and the castle of Ravenscraig in Fife. He was still Earl of Caithness and Lord Sinclair, and from the extent of his possessions one of the most powerful nobles in Scotland. Instead, however, of keeping these possessions united, he partitioned them among his three sons in such a way as contributed far more than the loss of the Orkneys to break down the family influence. On William, his eldest son, he bestowed merely the lands of Newburgh, in Aberdeenshire; on his second, Sir Oliver, he settled all his estates south of the Tay; while, with consent of the crown, he conveyed the earldom of Caithness to his youngest son, also named William.

Lords Sinclair.—The eldest son of this last Earl of Orkney endeavoured to set aside his father's settlement, by which he had been postponed to his younger brothers, and succeeded at last in effecting an arrangement by which Sir Oliver made over to him all the Fifeshire estates, while he renounced all claim to Rosslyn, and the other lands in the county of Edinburgh. He was still Lord Sinclair, and on his death, on the field of Flodden, he was succeeded by a line of Lords Sinclair, who ranked among the more considerable of the Scottish nobility. His grandson, by a daughter, was the notorious Earl of Bothwell, third husband of Queen Mary, and whom, in memory of his maternal descent, that unhappy queen created Duke of Orkney. The seventh Lord Sinclair had no male issue, but a daughter, married to St Clair of Herdmanston, the representative of the other House of Sinclair already alluded to. The son of this marriage, in virtue of a new patent obtained from Charles II., became eighth Lord Sinclair—this patent, singularly enough, bringing in, on failure of heirs male, his paternal relatives, the St Clairs of Herdmanston, strangers in blood to the former Lords Sinclair. The contingency provided for occurred in the next generation. The two sons of the eighth lord having died without issue, the title went to the Sinclairs of Herdmanston, who have ever since inherited it.

Earls of Rosslyn.—Rosslyn had been purchased by one of the sons of the eighth Lord Sinclair from the last of Sir Oliver's line, and while the title thus went to an entirely different line, the estates, both of Rosslyn and Dysart, were carried by destination to the issue of the eighth lord's second daughter, whose grandson, Sir James Erskine of Alva, succeeded to the earldom of Rosslyn, which had first been conferred on his maternal uncle, the Lord Chancellor Loughborough.

Sinclairs of Rosslyn.—Sir Oliver, the above-mentioned second son of the last Earl of Orkney, was progenitor of a line of barons who, for two centuries, owned the splendid domains of Rosslyn, and were buried in the vault of the chapel, in royal fashion, in their armour. Sir Oliver's second son was the noted Oliver Sinclair, the favourite of James V., whom, to the general disgust, he placed in command of the army sent to encounter the English in 1542. To the repugnance of the army to serve under him, is attributed the disgraceful rout of Solway Moss, where 10,000 Scottish troops fled at the sight of 300 English cavalry, to whom they can hardly be said to have made any resistance. Among the functions discharged by the Sinclairs of Rosslyn were those of protectors of the gipsy race, and hereditary grand-masters of the Masonic fraternity of Scotland. The last of Sir Oliver's line, impoverished by the political troubles in which his support of the Stewarts had involved him, sold Rosslyn, which then became, as has been already seen, the property of the disinherited elder branch.

Earls of Caithness.—This title was, as has been seen, conferred on William, the youngest son of the last Earl of Orkney, and has been ever since held by his descendants, passing repeatedly from one branch to another on the failure of the direct line. The third earl, ambitious enough to aspire to be an independent prince, endeavoured, in 1529, by force of arms, to recover the Orkneys from the crown. He was joined by his cousin, the second Lord Sinclair, but this foolish expedition met with a signal defeat. The support of the islanders had been calculated on: but the large majority of them turned out to be steady in their loyalty, and encountered the insurgents in a naval battle, in which the earl with 500 men were slain, and Lord Sinclair and the rest made prisoners. The sixth earl, having got into difficulties, conveyed his lands to his powerful creditor, Sir John Campbell of Glenurquhy, afterwards first Earl of Breadalbane, who, in 1677, got a patent creating him Earl of Caithness, and took possession of the Caithness estates. He was dispossessed, however, by George Sinclair, the heir-male, who entered Caithness with an armed force, and was eventually found to have the sole right to the title and estates. The Sinclairs of Ulbster are sprung from a legitimated son of William Sinclair, second son to the fourth Earl of Caithness, to whom the valuable and extensive lands of Ulbster were conveyed in 1596 and 1600 by the fifth earl. See Sinclair, Sir John.

A genealogical history of the St Clairs of Rosslyn, written by Father R. A. Hay, was printed privately at Edinburgh in 1835.

SINCLAIR, Sir John, an eminent agricultural improver, and patriotic Scottish gentleman, was born at Thurso Castle in 1754. He represented the Sinclairs of Ulbster, a branch of the noble House of Caithness. After a careful education, completed at Oxford, he studied law, and was admitted a member of both the Scottish and

English bars, but having, in his 16th year, succeeded to the family estate, he devoted himself to his duties as a northern landlord, and to the more engrossing pursuits of public life. In 1780, he was returned to parliament for his native county, which he represented for many years. He wrote pamphlets on public affairs—on the navy, the militia force, the national finances, &c. In 1784, he published a *History of the Revenue of the British Empire*, an elaborate work in two 4to vols.; and in 1786 he was created a baronet. He travelled over Europe, gathering information on economical and commercial questions, and on his return set about establishing a society in Scotland for improving the breeds of sheep and the quality of wool. His exertions also led to the formation of the Board of Agriculture in 1793, of which he was president for 13 years. This institution was the precursor of numerous agricultural associations, by which the country was greatly benefited. Sir John's most important undertaking was originating and carrying through the *Statistical Account of Scotland*, completed in the year 1798 in 20 large vols., and comprising a description of every parish in Scotland. The parochial clergy were the chief contributors, but the indefatigable baronet also employed statistical missionaries, and was for seven years actively engaged in prosecuting the work. Sir John wrote on all manner of topics, including even a tragedy, and treatises on health and longevity; and his publications during 50 years of ceaseless exertion are said to amount in number to 367! Not one of the whole seems destined to live; their value perished in the using; but the long and active life of their author was highly beneficial to his country. The venerable baronet died at Edinburgh, December 21, 1835, in the 82d year of his age.

Sir John S. left a numerous family, some of whom have attained to distinction. CATHERINE SINCLAIR, fourth daughter of the deceased baronet, was the author of a number of tales and descriptive works—*Modern Accomplishments, Modern Society, Scotland and the Scotch, Shetland and the Shetlanders*, &c., which all evince literary taste and talent, combined with fine moral feeling; while her practical benevolence and social kindness greatly endeared her to her friends, and to Edinburgh society generally. Miss S. died, universally regretted, in 1864, aged 63.

SINDE, an extensive province of British India, lies in the extreme west of that territory, and is bounded on the N. by Beloochistan and the Punjab, E. by Rajputana, W. by Beloochistan, and S. by the Arabian Sea and the Great Western Runn, an extensive lacustrine inlet which separates S. from Cutch. It is 380 miles in greatest length, 280 in greatest breadth from east to west, contains 54,403 English sq. m., with a pop. (1859) of 1,945,594. The sea-coast, which extends north-west for 150 miles, is very low and flat, with the sole exception of the small portion beyond Karatchi (Kurrachi), and is studded here and there with low mud-banks formed by the Indus, or with sand-hills, the accumulated drift from the beach; it is overflowed at high-tide to a considerable distance inland, and is hardly visible, according to Burnes, at a league from shore. The province is traversed through its whole length by the Indus (q. v.), which, on approaching the coast, divides and subdivides into a number of channels, forming a delta of 75 miles in length by 130 in breadth. This delta, unlike that of the Ganges, is almost wholly destitute of wood, and the soil consists of a mixture of clay, sand, and vegetable mould, which is speedily baked hard by the heat. Along each bank of the Indus is an alluvial tract of great fertility, extending 2 to 12 miles from the river, and mostly irrigated by artificial canals and watercourses, which, overflowing during the inundations, cover the soil with a silt so rich as to yield two, and sometimes three, crops in a year. The soil, nevertheless, contains in the north so much saltpetre, and in the south so much salt, that after the year's crops have been obtained, these substances are extracted for home consumption and export. Between the Indus and its most easterly branch, the Narra, is an alluvial 'doab,' averaging 75 miles in width, but which, from want of irrigation, has become almost a desert. East of this, on the other side of the Narra, is the *Thur*, a desert of shifting sand. West of the Indus the country is occupied by the desert of Shikarpur on the north, a desert not of sand, but of alluvial clay, the same as that of the delta, which only requires irrigation to render it fertile; and in the south it is traversed by the Hala Mountains. The *Thur*, or eastern desert, has numerous vestiges of former towns, in the shape of heaps of fragments of bricks and pottery. The climate of S. is remarkably sultry and dry, it being completely beyond the action of the south-west monsoon; at Haidarabad, the fall of rain in one year was $2\frac{1}{2}$ inches, and the average annual fall at Karatchi does not exceed 6—8 inches, and Larkhana has been known to be destitute of rain for three years in succession; the average maximum heat for six months at Haidarabad was 98·5° in the shade, and is still greater in Upper Sinde. There are generally two harvests per annum; the first, or *rubbî* (spring) harvest, consists of wheat, barley, oil-seeds, millet, durra, opium, hemp, and tobacco; the second, or *kurîf* (autumn) harvest, of those crops whose ripening requires much heat, as rice, sugar-cane, cotton, indigo, maize. The population consists of a mixture of Juts (a Hindu race) and Beluchis, with a few Afghans in the north-west; the greater portion of them are Mohammedans, and the remainder, who profess Hinduism, have fallen far from the strictness of observance which characterises the most of its followers. Generally, the Sindians are tall and handsome; the Beluchi portion of them warlike and independent; the Juts peaceable, and given to agricultural pursuits.

From the time (711) that S. was conquered by the calif, Abd-ul-Melek, it underwent numerous vicissitudes, forming at times a part of the empire of Delhi, and being latterly (1756) joined to Afghanistan. In 1779, the Beluchis rebelled, deposed their ruler, defeated the Afghans (1786), and raised their leader, the chief of the Talpûr tribe, to supreme power. This chief made large grants of territory to various of his relatives, reserving most of Lower S. for himself and his three brothers; so that there were four 'ameers' at Haidarabad, three at Khyerpûr, and one or two at Mirpur. The ameers of S. always regarded the British government with suspicion, and occasionally troubled those traders who visited their dominions; but they subsequently concluded commercial treaties, which were observed with punctuality. On the outbreak of the Afghan war in 1838, the British government intimated its intention to take temporary possession of Shikarpûr, and forced the ameers of Haidarabad and Mirpur to agree to a treaty which virtually destroyed their independence. Their expression of a natural dislike at the mode in which they had been treated, provoked fresh demands from the Calcutta government, to which the Haidarabad ameers agreed, despite the clamours and threats of their followers, who attacked the British residency on the following day. Sir Charles James Napier, the British envoy, at the head of a considerable military force, then marched against the enemy, totally routed them at Meeanee (17th February 1843), and by defeating the ameers of Mirpur, at Dubba, near Haidarabad (March 24th),

completed the subjugation of Sinde. The conquered territory was divided into three collectorates—Haidarabad, Karatchi, and Shikarpûr; the ameer of Khyerpûr, by continuing faithful to the British, retaining his dominions. For two years afterwards, Napier was actively employed in reducing the marauding tribes of the west, who pillaged the province; and so successful was the 'Sheitanka bhai' (Devil's Brother), as the robber tribes named him, that they were completely rooted out of their fastnesses, and most of them transported to distant regions. The country is reported as rapidly improving under its present administration.

SINDHU (from the Sanscrit *syand*, which in its older form probably was *syandh*, to trickle or flow) is the ancient name of the river Indus and the country along the Indus or Sindh.

SI'NDIA, the name of a powerful family of Mahratta chiefs and princes, which occupies a conspicuous place in the history of India during the 18th and 19th centuries. The founder of the family was RANOJEE SINDIA, a Sudra of the Kûmbi ('cultivator') tribe, who from a menial station in the household of the Peishwa, rose to a high rank in the body-guard, and after 1743, received in hereditary fief the half of the extensive province of Malwa. His son, MADHAJEE SINDIA (1750—1794), joined the Mahratta confederation, and was present at the battle of Paniput (1761), where he was so desperately injured as to be left for dead, but he speedily recovered, and on the retirement of the Afghans and their allies, repossessed himself of his hereditary dominions. On the death of Mulhar Rao Holkar (q. v.), he became the chief of the Mahratta princes, and had the command of the Peishwa's body-guard; and in 1770, the Peishwa and his two powerful feudatories, S. and Holkar, aided the emperor of Delhi in expelling the Sikhs from his territories, of which the administration was handed over to S., who was now by far the most powerful of the Mahratta chiefs. The murder of the young Peishwa by his uncle, Ragoba, and the consequent expulsion of the murderer from the throne he had seized, brought S. for the first time into collision with the British, who had espoused Ragoba's cause; but in the war (1779—1782) which followed, fortune distributed her favours with impartiality, and by the treaty of Salbye (1782), S. was recognised as a sovereign prince, and confirmed in all his possessions. In 1784, he captured the stronghold of Gwalior, and in the following year marched on Delhi, to restore his preponderance in the councils of the puppet monarch, and subsequently seized Agra, Allyghur, and nearly the whole of the Doab (q. v.). The manifold advantages of European discipline had struck him forcibly during the war with the British, and, with the aid of an able French officer, he introduced it into his own army. An army of 18,000 regular and 6000 irregular infantry, 2000 irregular and 600 Persian horse, with 200 cannon, was accordingly raised, and under the leadership of De Boigne, the officer above noticed, reduced Joudpore, Odeypore, and Jypore, three Rajpût states, and effectually humbled the pride of Holkar.—DOWLUT RAO SINDIA (1794—1827) continued his grand-uncle's policy, and during the troubles which convulsed Holkar's dominions at the commencement of the 19th c., he ravaged Indore and Poona, but was wholly routed in 1802 by Jeswunt Rao Holkar. Having joined Bhonsla, the rajah of Berar, in a raid on the Nizam (1803), he brought down upon himself the vengeance of the East India Company. The confederated Mahrattas were routed at Assaye and Argaum by Sir Arthur Wellesley; S.'s disciplined troops, under the command of French officers, were scattered irretrievably at Patpergunge (near Delhi) and Laswari by Lord Lake, and he only escaped total ruin by acceding to a treaty by which all his possessions in the Doab and along the right bank of the Jumna were ceded to the British. Gwalior was, however, restored in 1805, and from this time became the capital of S.'s dominions. S. had been taught by his reverses a useful lesson, and he declined to join Holkar, the Peishwa, and Bhonsla, in their attack (1817) on the British, and thus escaped the swift destruction which was visited upon his turbulent neighbours. During the reign of BHAGERUT RAO SINDIA, a minor, the Gwalior dominions were in such a state of anarchy, that the British were compelled to insist on certain guarantees for the preservation of tranquillity; and on these being rejected, a war followed, and the Mahrattas were routed at Maharajpûr (December 29, 1843) by Lord Gough, and at Puniaur by Major-general Grey on the same day. Gwalior fell into the hands of the British, 4th January 1844, and S. submitted to the conditions demanded of him, besides maintaining a contingent force of sepoys at Gwalior. In 1853, he was declared of age by the East India Company, and in 1858 he took the field at the head of his own army against the Gwalior contingent, which had joined in the great sepoy mutiny. But the most of his troops deserted him during the battle (June 1), and he narrowly escaped by fleeing to Agra. S. was subsequently reinstated by Sir Hugh Rose, and received from the British government numerous testimonials of its grateful respect for his faithfulness as an ally.

SI'NECURE (Lat. *sine cura*, without care), in common language, an office which has revenue without employment. In the canon law, a sinecure is an ecclesiastical benefice, such as a chaplainry, canonry, or chantry, to which no spiritual function is attached, except reading prayers and singing, and where residence is not required. The strictest kind of sinecure is where the benefice is a donative, and is conferred by the patron expressly without cure of souls, the cure either not existing, or being committed to a vicar. Sinecure rectories were abolished by 3 and 4 Vict. c. 113, s. 48.

SI'NEW. See TENDON.

SINGAPO'RE, one of the Straits Settlements (q. v.), belonging to Great Britain, consists of an island lying off the south extremity of the peninsula of Malacca, in lat. about 1° 17′ N., long. 103° 50′ E., and having a city of the same name on its south side. The island is 25 miles long, and from 11 to 15 broad; area, 206 sq. miles. It is separated from the mainland by a narrow but deep strait, varying from a mile to a few furlongs in width. The surface is generally low and undulating, the greatest elevation (Bukit Tima, or the Hill of Tin) being only 520 feet. According to Malay accounts, a colony was planted on the site of the present town by tribes who are inferred to have been Javanese, from the circumstance that the name Singapura, which they gave to their settlement, is most probably of Sanscrit origin (lion-town); the Javanese being the only people in these seas who have become fairly Hinduised. Be that as it may, in 1818 it was found by Sir Stamford Raffles to be an island covered with primeval forests, sheltering in its creeks and rivers only a few miserable fishermen and pirates. It seems to have been unclaimed by any power until 1811, when the Sultan of Jahore formally annexed it to his territories. The commanding position of S., in the very centre of the highway leading from British India to China, led

Sir Stamford Raffles to mark it out as the site of the first free port in the Malayan seas; and in 1819, the British flag was hoisted on the new settlement; although it was not till 1824 that Mr Crawford concluded a satisfactory treaty with the Sultan of Jahore, whereby the island of S., and all the islands within 10 miles of its shore, were given up in full sovereignty to the East India Company. In April, 1867, it was transferred from the Indian government to the Colonial Department. Its position as an entrepôt for the trade of the Malayan Archipelago, the Eastern Peninsula, and China, and the wise policy that placed the commerce of the new port on an entirely unfettered footing, rapidly established a flourishing trade. In 1823, the imports amounted to £1,200,000; the exports to £920,000. In the year ending 30th April 1865, the value of the imports was £6,610,000; the exports, £6,630,000, being fully double the amounts in 1854—1855; and notwithstanding the recent opening up to more direct communication with Europe of many of the markets in China, Cochin-China, and Siam, hitherto largely supplied by traders from S., a steady increase in the trade of the port is still confidently looked for. The following list shews the chief countries with which this large trade was carried on in 1864—1865:

VALUE OF EXPORTS.

	Rupees.
Great Britain,	9,886,969
North America,	1,809,478
Calcutta,	10,597,455
China,	11,558,408
Cochin-China and Siam,	9,143,833
Java, Rhio, Bally, &c.,	3,954,654
Malay Peninsula and British Burmah,	3,763,865
Miscellaneous,	15,702,716
Total rupees,	66,417,378

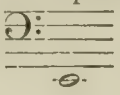
VALUE OF IMPORTS.

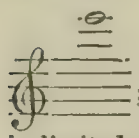
	Rupees.
Great Britain,	18,353,150
Calcutta,	4,606,085
China,	8,346,969
Cochin-China and Siam,	3,523,024
Java, Rhio, Bally, &c.,	7,056,244
Sumatra,	1,467,741
Malay Peninsula and British Burmah,	5,897,278
Miscellaneous,	16,931,596
Total rupees,	66,182,087

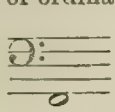
The chief articles of export to Europe and North America are gambir, tin, sago, tapioca, black and white pepper, tortoise-shell, nutmegs, gutta-percha, camphor, coffee, sapan-wood, and rattans. Of these, only gambir, sago, and nutmegs are produced on the island to any important extent; all the other articles being imported, chiefly by natives from other quarters. From Europe, large imports are received of cotton manufactures, woollens and linen, metals, hardware, earthenware, arms and ammunition, and treasure in the form of dollars. Large fleets of prahus are wafted by the southerly monsoon towards this great centre of trade, laden with the numerous products of the Indian Archipelago, to return again laden with the manufactures of Europe. Exclusive of the vast number of native craft, the square-rigged vessels that entered the port in 1864—1865 numbered 1697, with a tonnage of 780,794; the number that cleared was 1629 vessels, of 578,527 tons.

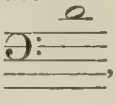
The currency of commerce is the Spanish dollar; but the official currency of government is the rupee. The Chinese pecul, of 133⅓ lbs. avoirdupois, which is divided into 100 catties, is the standard of weight. The population of S. is perhaps the most heterogeneous in the world, comprising at least 16 nationalities, speaking different tongues. The Malay, however, soft and easily acquired, is the recognised medium of communication between all classes. The population of S. has been lately estimated as under:

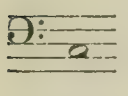
Europeans and their descendants,	1,000
Chinese,	60,000
Malays,	13,000
Various natives of Continental India,	12,800
Other Asiatics,	7,000
Total,	93,800

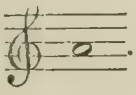


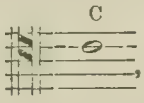


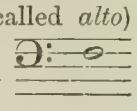


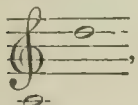


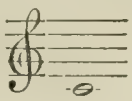


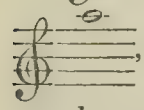


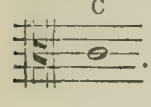










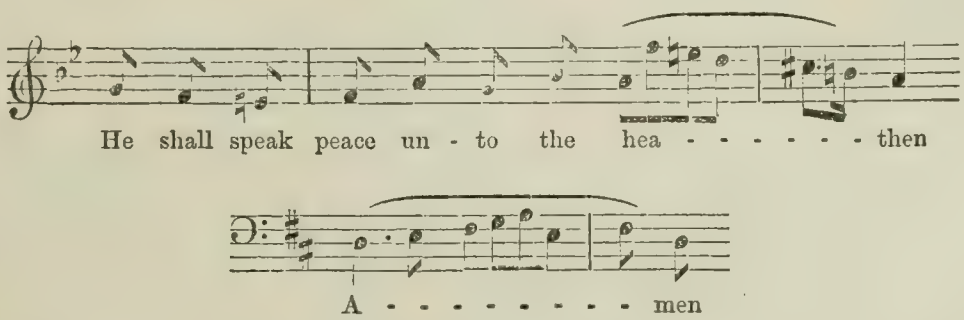


Of the aboriginal inhabitants of the island, not a trace remains, but similar tribes are still to be found in small numbers in several parts of the peninsula. Of the native population, the Chinese are the most useful part; they form almost the only body of trustworthy native merchants, in the proper sense of the word, and are freely trusted to large amounts by European importers; and it may be doubted whether, as a commercial body, they are, on the whole, more deficient in morality than many European communities. The government of S. is presided over by the governor of the Straits Settlements (q. v.). The laws are those of Great Britain, with some modifications; the court is that of a recorder. S. being a free port, the revenue is raised by inland excises on opium and spirits. Negotiations have for some time been going on for the transference of the entire government of the Straits Settlements to the Colonial Office.

The town of S., which contains nine-tenths of the whole population of the settlement, is situated at the mouth of a small river, on the south side of the island. Its appearance is of a mixed oriental and European character; the streets are generally wide, and kept in good order, and in 1864 the town was lighted with gas. There is an efficient police, and the sanitary arrangements of the town are good. The municipal council consists of public officers and ratepayers; the municipal revenue is raised by a rate on houses and land, and on horses and carriages.

S. possesses two fine harbours; one opposite the town, which, although little more than an open roadstead, is a safe and convenient anchorage, where ships load and discharge by means of lighters; the other is about 3 miles west of the town, and is land-locked, and capable of admitting the largest vessels. Along its shores, extensive wharfs have been erected by steam-companies and individual merchants; and it is probable that when communication by railway with the town is established, the old harbour will be little used. There are several fortifications commanding the harbour and roads, but the increasing commercial and political importance of the place calls for a still stronger naval and military station. S. being within 80 miles of the equator, has little or no variety of seasons; the climate, although hot, is healthy; the temperature ranges from 71° to 92°; rain falls more or less on 200 days of the year, and the extent of the fall is about 87 inches. The soil of S. is not fertile, although the climate is such as to cover it with a rich and beautiful vegetation. The nutmeg was at one time successfully cultivated, but most of the trees having unaccountably died, this has been abandoned, and husbandry is now confined to the cultivation of the cocoa-nut, the pepper-vine and gambir plant, and to the raising of sugar-cane and vegetables for local consumption. The curse of S. is the tiger. It is estimated that 300 Chinamen and other natives are carried off yearly. Turtle are abundant on the shores, and form the cheapest animal food in the bazaars.—See Thomson's *Journal of the Indian Archipelago;* J. Crawford's *Dictionary of the Indian Islands and Adjacent Countries;* J. Cameron's *Our Tropical Possessions in Malayan India.*

SINGHARA NUT. See TRAPA.



SINGING, the art of producing music from the human voice, generally, though not necessarily, combined with speech. The mechanism of the vocal organs, as applicable to singing, has by some physiologists been likened to a reed, by others to a stringed instrument; in point of fact, the human voice is produced by an apparatus far beyond either in complexity of structure.

The extreme limits of the voice in respect of pitch may be considered to be from  to  ; but the compass of any individual voice is limited to a portion of that range, and voices are classified according to their pitch. Generally speaking, male voices lie an octave below female. The former are divided into *bass* and *tenor*, the compass of ordinary bass voices being considered to be from  to  , and of tenor from  to  . For tenor music, the tenor or C clef is generally used,  , which has the advantage of having the principal tones within the staff. When the treble clef is used, the music is written an octave above its true pitch. Female voices are either *contralto* (otherwise called *alto*) or *soprano*, the former extending from  to  , the latter from  to  , or sometimes higher. Contralto music may be noted either on the treble clef, or on the alto clef, which latter is but the tenor clef placed on the third instead of the fourth line of the staff  . These are the principal divisions of voices; but there are also further subdivisions. Intermediate between base and tenor is another male voice, called *baryton;* and intermediate between contralto and soprano, another female voice, called *mezzo soprano*. The ordinary compass of a voice is about twelve notes, but two octaves are not uncommon, and some voices have reached three. Madame Catalani is said to have possessed a voice of three and a half octaves compass.

The notes produced in singing are of two kinds, according as they proceed from the chest voice (*voce di petto*), or head voice (*voce di testa*). The chest notes, or lower register, proceed naturally and readily from the ordinary mechanism of the voice; the upper register, head voice, or falsetto, is produced by a more or less forced contraction of the cavity from which the voice proceeds, imparting to the notes a fife-like character, gentle and weak in the male voice, but often clear and sonorous in the female. It is only in the higher notes of the voice that the falsetto is used, and some notes on the borders of the two registers may be given in either. Where the two registers meet, the tones are apt to be hard and uncertain, or weak; but a cultivated singer will blend the head and chest voice at the point of junction, so as to make the break imperceptible. The notes of the bass voice are given entirely from the chest. In the tenor, the three or four upper notes belong mostly to head voice. The contralto tones are mostly chest voice, and the upper tones of the soprano are head voice. The alto, when sung, as it often is in England, by male voices, is principally falsetto.

In singing, the head should be held erect, and the chest well expanded, to allow free play to the lungs, and free emission of the voice from the throat. The tongue should be kept still, slightly pressing on the lower teeth. Proper regulation of the breath, and proper articulation of the words, are also matters of essential moment.

One particular requires to be mentioned, in which the notation of songs differs from that of instrumental music. In the latter, two or more quavers or semiquavers may be grouped together by a common line; in singing, this can only be done when the whole group are to be sung to one syllable, and notes belonging to different syllables are always written separately. When notes without hooks, or notes that are not grouped, belong to one syllable, they are bound together by a *slur* placed over them, e. g.:

Among the principal objects to be studied in cultivating the voice for singing are the improvement of its quality in respect of clearness and resources; the rendering every note in its compass equally pure; the extension of its compass, not by injudicious forcing, but by gradual practice; and the acquirement of the power to prolong any note with perfect ease. See MUSIC, VOICE, SOLFEGGIO.

SI'NGULAR SUCCE'SSOR, in the Law of Scotland, means one who succeeds in the ownership of property by purchase or any other mode than by descent.

SINIGA'GLIA, or SENIGALLIA (anc. *Sena-Gallia*), a city and seaport on the east coast of Italy, in the province of Ancona, and 17 miles west-north-west of the city of that name, at the mouth of the Misa, with 10,501 inhabitants. It is a bright, cheerful city, built after the modern style, walled round, and it has bastions and handsome gates. S. is celebrated for its annual fair, which lasts from the 20th July to the 10th August, and which

sometimes puts in circulation about 60 million francs in 20 days. English, French, Swiss, Americans, Germans, &c., attend it. S. was founded by the Senonian Gauls, and colonised by the Romans 289 B. C.

SI'NISTER, in Heraldry, the left-hand side of a shield. As shields are supposed to be carried in front of the person, the sinister side is that which covers the bearer's left side, and therefore lies to the spectator's right. See POINTS OF ESCUTCHEON.

SINKING FUND. See FUND.

SINO'PÉ (Turk. *Sinub*), a town of Asiatic Turkey, province of Anatolia, on the southern side of a little promontory running eastward into the Black Sea, 80 miles north-west of Samsun. S., which is defended by some half-ruined fortifications, possesses a dock-yard and naval arsenal; exports timber, salt, cordage, fish, and oil, and has a population variously estimated at from 4000 to 12,000. The bay of S., which affords the finest anchorage for ships along the whole northern coast of Asiatic Turkey, was the scene of a bloody naval engagement, or rather massacre, 30th November 1853, when a Turkish squadron of 13 ships was suddenly attacked and destroyed by the Russian fleet.—Of the ancient city of S., which was founded by a colony of Milesian Greeks, and, for 200 years after the Peloponnesian war, was almost the mistress of the Euxine, numerous ruins still exist, 'friezes, hundreds of Corinthian columns, capitals, sculptures, inscriptions, and even statues, built up into the walls of its picturesque Byzantine fortifications.' S. was the birthplace of Diogenes the cynic.

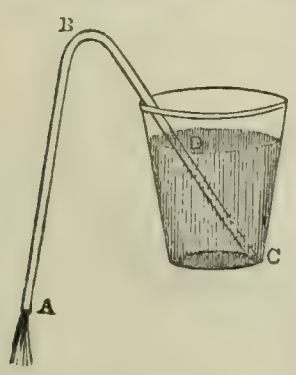
SI'NOPLE, in Heraldry, the same as VERT (q. v.).

SI'NTER, the name given by German mineralogists to those rocks which are precipitated in a crystalline form from mineral waters. They are of recent date, belonging in fact to the strata at present in course of formation. S. is of various forms, kidney-shaped, knotted, tuberous, botryoidal, tubular, stalactitic, shrub-like, or pronged, and is occasionally distinguished by its chief component, as Calcareous S., Flint or Quartz S., Iron S., &c. Calcareous S., which is a variety of carbonate of lime, composed of concentric plane parallel layers, appears under various forms; it is deposited with extraordinary rapidity by many springs, a peculiarity frequently made use of to obtain the incrustation of objects with a coating of this substance. Quartz S. is mostly found in intermittent hot springs, as in the Geysers (q. v.) of Iceland. Iron S. occurs in old mines, and in coal-beds, where it is formed from iron pyrites through the agency of the atmosphere. The tubular conglomeration of grains of sand half-melted by lightning (*blitz*) is also known as Blitz-S., or Fulgurite (q. v.).

SI'NUS (Lat. a bend or hollow) has two significations in Anatomy, and one in Surgery. The cells or cavities contained in certain bones—as the frontal, ethmoid, sphenoid, and superior maxillary—receive this designation. The frontal sinuses are two irregular cavities extending upwards and outwards, from their openings on each side of the nasal spine, between the inner and outer layers of the skull, and separated from one another by a thin bony septum. They give rise to the prominences above the root of the nose called the nasal eminences. They are not developed till after puberty, and vary considerably in size, being usually larger in men than in women and young persons, in consequence of the greater prominence of the superciliary ridges in the former. When very much developed, they give a receding appearance to the forehead. They are larger in Europeans than in negroes, and are very imperfectly developed in the Australians, whose peculiar want of vocal resonance is apparently due to this deficiency. They communicate on each side with the upper part of the nostril by a funnel-shaped opening, which transmits a prolongation of mucous membrane to line their interior. These cells are much more highly developed in certain mammals and birds than in man. Professor Owen observes that 'they extend backwards over the top of the skull in the ruminant and some other quadrupeds, and penetrate the cores of the horns in oxen, sheep, and a few antelopes. The most remarkable development of air-cells in the mammalian class is presented by the elephant; the intellectual physiognomy of this huge quadruped being caused, as in the owl, not by the actual capacity of the brain-case, but by the enormous extent of the pneumatic cellular structure between the outer and inner plates of the skull.' The sphenoidal sinuses are two large irregular cavities, formed, after the period of childhood, in the body of the sphenoid bone. They communicate with the upper part of the nose, from which they receive a layer of mucous membrane. Like the frontal sinuses, they serve to lessen the weight of the skull, and to add to the resonance of the voice. The ethmoid sinuses or cells lie in the lateral masses of the ethmoid bone. They open into the cavities of the nose. Their main use is to diminish the weight of the fore-part of the skull. The superior maxillary sinus commonly known as the *Antrum of Highmore* (the anatomist who first accurately described it) is the largest of the facial sinuses. Its uses are the same as those of the others, and like them, it communicates with the nasal cavities.

The *sinuses of the dura mater* are quite distinct from the above-described bony sinuses; they are irregular channels for the transmission of venous blood, and are formed in the following way. The dura mater consists of two layers—an outer, belonging to the skull; and an inner, belonging to the brain. They can be easily separated in infancy, but in the adult they are blended together for the greater part of their extent. In some places, however, as beneath the sagittal suture (formed by the two parietal bones at the top of the head, and running from before backwards), they are separated on either side of the mesial line, the outer layer being continued beneath the bone, and in contact with it; while the inner one dips inwards, and meeting with the corresponding layer of the opposite side, forms a triangular canal or sinus, which is strengthened at the sides and angles by interlacing bands of fibrous tissue. The sinus whose formation we have thus described is called the superior longitudinal sinus, and the other sinuses are formed in the same way. They are all lodged in the intervals between the great divisions of the brain, and they are so constructed 'that their shape cannot easily be altered by any external pressure; consequently, the flow of blood through them cannot be impeded by the pulsations or pressure of the brain, in the varying positions of the body. The tense, unyielding character of their walls, moreover, does not admit of either collapse or distention; hence, they must be equally full at all times, and must exert a uniform pressure on the brain.'—Humphry *On the Human Skeleton*. p. 200.

In Surgery, the term *sinus* is nearly equivalent to *Fistula* (q. v.).



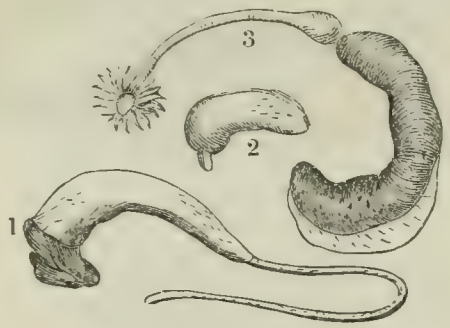
SION, a small town of Switzerland, capital of the canton of Valais, in a picturesque situation on the right bank of the Rhone, 18 miles north-east of Martigny by the Simplon Railway, of which it is the termination. It is defended by walls, towers, and a ditch, and contains a large cathedral and a handsome Gothic town-house. On the north of the

town is a lofty rock, divided into two peaks by a deeply-cut ravine. On the highest peak is the ruined castle of Tourbillon, built in 1294; on the other, the castle of Valeria, now used as a seminary. An excellent wine, called Malvoise, is made here. S. is called *Civitas Sedunorum* in a still existing inscription in honour of Augustus, to be seen in the cathedral; in the middle ages it was named *Sedunum*. Pop. about 3000.

SIOU'T, also *Es-Sioût*, and *Osiût*, the chief city of Upper Egypt, stands near the western bank of the Nile, and is 200 miles in direct line south of Cairo. It has several fine mosques, bazaars almost as well furnished as those of the capital, some good baths, and one or two well-built houses. S. manufactures great quantities of the best pipe-bowls. It is the residence of the governor of Upper Egypt; the resort of the caravans from Darfur, that come by the way of the Great Oasis, and until recently was the principal seat of the Egyptian slave-trade. Pop. about 25,000. S. is built on the site of the ancient Lycopolis, but few remains of the Græco-Egyptian city are extant. From the neighbouring heights of the Libyan mountains, which contain numerous rock-sepulchres, the view over the valley of the Nile is, in the opinion of Lepsius, the finest in Egypt.

SIOU'X, a tribe of North American Indians, calling themselves also Dacotahs, inhabiting Dakota territory. They are a brave and warlike people, generally at war with the Chippeways. Formerly they numbered 30,000, and counted 7000 warriors; at present their whole number is estimated at 23,250. Roman Catholic missions were established among them 200 years ago, and Presbyterian missions more recently, and they are farther advanced towards civilisation than any other tribe of the North-west.

SI'PHON is a tube bent so that the two legs are either parallel, or incline at an acute angle, and is employed to draw off liquids from vessels which it is not convenient or desirable to move. If the end of the short leg of a siphon be plunged into the liquid, and the other leg be suffered to hang outside the vessel, then, whenever the siphon is exhausted of air (a process which can be performed by suction by the mouth or a pump, or by filling the tube with the liquid it is employed to decant, and keeping it so filled till it is placed in its proper position), the liquid will at once flow out of the vessel through the tube, and continue to do so either till it falls below the level of the outside end, or till the inside end ceases to be immersed.



Siphon.

The principle of this simple and efficient instrument is easy of explanation: let ABC (fig.) be a siphon with one leg, BC, partially immersed in liquid, and suppose the whole siphon filled with the same liquid; then at A we have the pressure of the atmosphere acting upwards into the tube in opposition to the pressure of the liquid in the leg BA; at C we have the pressure of the atmosphere (transmitted through the liquid), and the pressure of the liquid in the vessel outside (which balances an equal height of liquid inside) the tube, acting upwards into the tube in opposition to the pressure downwards of the liquid in the leg BC. The effective pressures inwards at A and C are, respectively, the atmospheric pressure less by the pressure of the liquid in BA, and the atmospheric pressure less by the pressure of the liquid in BD; and as the latter of these two is the greater, it overcomes the other, forces the liquid in the tube out at A, and that in the vessel into the tube at C, the process continuing till the liquid falls to the level of C (when air is admitted), or of A (when the two pressures become equal). It is evident from the above explanation that when A is on or above the level of D, the surface of the fluid, there can be no flow through the tube; also, that it is quite immaterial whether the longer or the shorter leg be immersed, if only A be below the level of D. If the bend of the siphon be 33 feet for water, or 30 inches for mercury, above D, the pressure at C, which produces the action of the siphon, becomes the weight of the atmosphere, diminished by an equal weight of a column of fluid, in which case the resulting pressure is zero, and there is no flow through the tube. The flow increases in rapidity and force as the difference of level between D and A increases, and as the difference of level between D and B diminishes. Many siphons have a suction-pump permanently attached to the end of the outer leg for the purpose of exhausting the air inside. Another variety is the *Wurtemberg siphon*, which has two equal legs, the extremities of which are bent upwards, so that when the siphon is once filled with fluid, it remains full, and is always ready for use.

SIPHONO'STOMA. See FISH-LOUSE.

SIPHONOSTO'MATA, a large group of gasteropodous molluscs, of the order *Pectinibranchiata*, having the mantle prolonged into a siphon, by which the water enters the gill-chamber. The shell is spiral, the aperture notched or produced into a canal in front, often much produced. To this group belong the families *Cypræidæ* (cowries, &c.), *Volutidæ*, *Buccinidæ* (whelks, &c.), *Muricidæ*, and *Strombidæ*. They are almost all carnivorous, and move about with considerable activity.

SIPU'NCULUS, a genus of *Echinodermata*, giving its name to a family, *Sipunculaceæ*, and to an order, *Sipunculidæ*. The *Sipunculidæ*, although ranked among the *Radiata*, and having the essential characters of that division of the animal kingdom,

Sipunculus Bernhardus:
1, Sipunculus alive in a periwinkle shell, with the upper part of the shell broken away to shew the animal's body; 2, S freed from its shell, with the trunk retracted; 3, S. with all its parts expanded, as when preserved in spirits.—From Forbes's *British Star-fishes*.

resemble the *Annelida* in form, general appearance, motions, and habits, as well as in their softer covering, which is leathery and not calcareous, and in the absence of calcareous spines. The *Sipunculaceæ* have a retractile proboscis, around the extremity of which is a circle of tentacula, and at the base of it the anus. In the genus *Sipunculus* the proboscis is long and cylindrical, with a circle of tentacula near its extremity. *S. Bernhardus* is common on many parts of the British coast, living at the bottom of the sea, at a depth of from ten to thirty fathoms, and occupying as a habitation the shell of

some univalve mollusc, for the protection of its soft wormlike body. It secures the entrance of the shell by a plaster-work of sand, leaving only a hole wide enough for the protrusion of its long flexible proboscis. Other species, instead of sheltering themselves in shells, burrow in the sand. Among these is the EDIBLE S. (*S. edulis*), much esteemed by the Chinese.

SIR (Fr. *sieur* and *sire*, contracted from *seigneur*; from Lat. *senior*, elder), a term originally corresponding to *dominus* in Latin, and which has come, when appended to the Christian name and surname, to be the distinctive mark of knighthood. It was at one time the practice to use the same title in addressing the clergy, a familiar instance being Sir Hugh Evans in the *Merry Wives of Windsor*. To so great an extent did this usage obtain, that a 'Sir John' came to be a common sobriquet for a priest. 'Sir' was here a translation of *dominus*, the term used for a bachelor of arts, originally in contradistinction from the *magister*, or master of arts, but eventually extended to the clergy without distinction. Used along with the Christian name and surname, 'sir' is now applied exclusively to knights and baronets. Standing alone, it is a common complimentary mode of address used without much consideration of rank or social status. 'Sire' is another form of the same monosyllable, which has been adopted from France as a mode of addressing royalty.

SIR-DA'RIA. See JAXARTES.

SI'REN, a genus of trachystomatous batrachia, of eel-like form, but having two small weak limbs on the fore part of the body. Each foot has four toes. There is no vestige of a hinder pair of feet, nor of a pelvis. The vertebræ are numerous, and each of the vertebræ of the body carries a pair of short

Siren Lacertina.

ribs. The vertebræ of the tail are compressed, and gradually diminish in size to its tip. The head is flattened, the mouth not deeply cleft, the muzzle blunt, the eyes very small, the ears concealed. The teeth are small; the lower jaw is furnished with them all round; there are none on the upper jaw, but two rows on each side of the palate. On each side of the neck are three gills, each consisting of a short fleshy stalk, supporting a beautiful fringe-like tuft, and water passes from the mouth to the gills through openings as in fishes. But the S. has also lungs, which are long bags, one on each side, beginning behind the heart, and extending almost the whole length of the abdomen. The blood discs are remarkable for their large size, exceeding even those of the proteus. The sirens inhabit the swamps of the Carolinas and other southern parts of North America. They live chiefly in the mud, but sometimes are to be seen swimming in the water, and even make excursions on moist ground. They feed on worms and insects. *S. lacertina* grows to the length of about three feet. Its colour is blackish. The tail is compressed. The other species are smaller.

SIRÈNE, an instrument for the production of musical sounds in such a manner as to enable us to discover their ultimate nature. The simplest form of sirène is represented in section in fig. 1. A vane consisting of four equal plates, attached to a delicately supported axle, is so fixed in a metal tube as to close it almost completely (with the help of stops P, P), when either pair of plates is perpendicular to the axis of the tube. When air is forced from a bellows through the pipe A, it gives the vane a rotation in the direction indicated by the arrow, and thus produces a current which is interrupted four times in each revolution. In other words, four times in each revolution the air escapes freely, giving rise to a sound. While the vane revolves slowly, the ear distinguishes these successive puffs; but when the revolutions are more numerous than about five per second, the successive puffs cannot be distinguished, and the recurrent sounds are merged into a uniform note, whose pitch rises (i. e., it becomes more and more shrill) the faster the vane revolves. Such an instrument works well when driven by water instead of air. What it shews is, that musical sounds consist of the repetition, at equal very small intervals of time, of some definite noise. By turning the vane by means of a train of wheels, so as to give it a definite rate of rotation, the number of such repetitions per second, necessary for the production of a given musical note, may be measured.

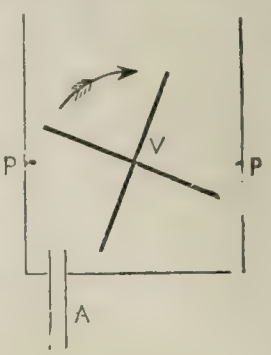


Fig. 1.

But the sirène of Cagniard de la Tour is much more valuable for such a purpose, as it counts for itself the number of repetitions per second. In principle, it is identical with the simpler instrument just described; but the details of its construction are different. It consists essentially of two circular discs, the upper of which is free to revolve so as almost to touch the lower (fig. 2). In each a series of holes is cut, arranged at equal distances in a circle about its axis. Through the holes in the lower (fixed) plate, streams of air are admitted from a bellows,

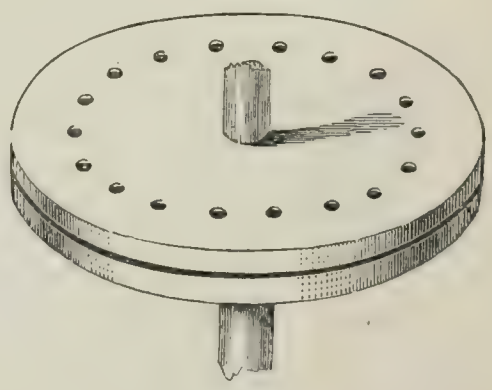

Fig. 2.

and pass through the corresponding holes in the upper (movable) plate, when the pairs of holes are superposed; but are checked when the upper plate is turned a little, readmitted when the plate turns a little further, and so on. The holes are pierced *obliquely* through the upper plate, so that the issuing

stream makes it turn about its axis. The sounds given by this instrument are exceedingly pure (see SOUND), like those of the flute or tuning-fork. The axis of the upper plate carries an endless screw, which turns a light train of wheels (with dials) resembling that of a gas meter, so that when, by proper adjustment of the pressure in the bellows, the instrument gives steadily some definite note, we may observe the number of turns in any number of minutes by watch. The number of puffs is obviously to be found from this by multiplying by the number of holes in the plate, since during one turn any hole in the upper plate has been opposite each of those in the lower plate in succession. Thus we find the number of puffs per second necessary to the formation of any given musical note.

More complex forms, such as Helmholtz's double sirène, have been devised for more recondite branches of the science. See SOUND.

SI'RENS (Gr. *seirēnes*, the 'entanglers,' probably from *seira*, 'a cord' or 'string') figure in Greek mythology as young maidens, who sat on the shores of a certain island or promontory near the south-western coast of Italy, and sang with bewitching sweetness songs that allured the passing sailor to draw near, but only to meet with death. Homer speaks of them in the plural, but does not specify their number; later writers mention two and three by name, and assign them various genealogies. Their tenure of life was dependent on the successful exercise of their charms. If any seaman could resist the enticements of their magic music, they were doomed, but Ulysses or the Argonauts alone succeeded in doing so. It is related by Homer, in the *Odyssey*, that when the former in the course of his wanderings approached their perilous home, he, by the advice of the sorceress Circe, stuffed the ears of his companions with wax, and lashed himself to a mast, until he had sailed out of hearing of the fatal songs. Others say that it was the Argonauts who got safely past, owing to the superior enchantment of Orpheus's singing, whereupon the S. threw themselves into the sea, and were transformed into rocks. The Latin poets give them wings, and in works of art they are often represented as birds with the faces of virgins, and are provided with musical instruments. There is obviously a close resemblance between the Mermaid (q. v.) of northern mythology, and these Græco-Mediterranean Sirens. The Loreley of the Rhine is only a river-siren, though a more exquisite enchantress than ever Greek fancy conceived.

SIRINAGUR. See SERINAGUR.

SI'RIUS, otherwise called *Canicula*, or the *Dog-star*, is a star of the first magnitude, the brightest in the heavens, and is situated in the constellation of *Canis Major*, or the 'Great Dog.' It is about 123 billions of miles distant from the earth. See STARS. It has long been known to possess a 'proper motion' (i. e., an independent progressive motion), which was for a time believed to be in a straight line, but has now been shewn to consist of an undulatory progressive motion on each side of a middle line. This motion was investigated by Professor Peters of the Pulkowa Observatory, Russia, on the supposition that its anomalous character was produced by the attraction of some unseen neighbour, and his calculations being completed and verified (on this supposition) by Mr Safford of Washington, the distance of S. from the centre of gravity of both was determined to be 1495 millions of miles. In January 1862, Mr Alvan Clark of New York, chancing to observe S. through a powerful telescope, detected a minute star (which had never before been observed) situated at an angular distance of 7″ from S., representing about 4300 millions of miles, and it is generally believed that this is the disturber in question. By photometric measurement it has been shewn that, supposing the intensity of the sun's light for unit of surface to equal that of S., it would require 400 suns at the distance of S. to send us the light which that star does. The parallax of S. has been determined to be 0″.23, and its distance from the earth is therefore probably 156,000,000,000 miles. The Egyptians called this star Sothis, and at one time its 'heliacal rising' (q. v.) was a sure forerunner of the rising of the Nile; while among the Romans it was considered as a star of evil omen, whose appearance above the horizon coincided with (or even caused) the unhealthy and oppressive heats of summer. Hence the origin of the various superstitions regarding the Dog Days (q. v.), many of which are still current.—The term 'dog star' was also applied to Procyon, a bright star in *Canis Minor*, whose heliacal rising differs only by a few days from that of Sirius.

SIRO'CCO. See SIMOOM.

SISMONDI, JEAN CHARLES LEONARD DE, a distinguished historian of Italian descent, was born at Geneva on 9th May 1773. He received his education as a boy at the 'College' or high school of his native town. At the due age, he was removed to the Auditoire, or university. Before he had completed his education, the pecuniary reverses of his father made it necessary for S. to do something for his own maintenance, for which purpose he entered the counting-house of the eminent firm of Eynard and Co. of Lyon. Hateful as mercantile pursuits seem to have been to him, he applied himself to his drudgery with all diligence. He became a thoroughly good clerk, and in after life he acknowledged that the practical training had been of incalculable benefit to him. The French revolution sent S. back to Geneva, but the storm following, he took refuge in England, along with his family. Home-sickness soon sent them back to Geneva, but the continuance of political trouble made it impossible to remain there long. In 1795, they bought a small farm near Pescia, in Tuscany, where their narrow circumstances rendered it necessary for S. almost literally to put his hand to the plough. He had now, however, leisure for literature. In 1798, he began to collect materials for his *History of the Italian Republics*. In 1803, appeared a work on political economy, *De la Richesse Commerciale*, in which he writes like a decided follower of Adam Smith, though at a later period, in his *Nouveaux Principes d'Économie Politique* (1819), he abandoned the wiser views of his youth. In consequence, a professorship in this science was in the same year offered to him in the university of Wilna, which he declined. It was in history, however, that his literary forte lay. The 16 vols. of his *Histoire des Républiques Italiennes*, published between 1807 and 1818, placed him in the first rank among contemporary historians, and brought him praise from the most distinguished men in France and Germany. The events of the Hundred Days occasioned one of the most memorable passages in the life of S.—his interview with Napoleon. In 1813 appeared his *Littérature du Midi de l'Europe* ('Literature of the South of Europe,' Eng. by Roscoe, frequently reprinted). In 1819, he began his best and greatest work, the *Histoire des Français*, with which he was occupied until his death. On the 19th April of the same year he married Miss Allen, an English lady, whom he had previously met in Italy. This marriage was followed by many happy

years, during which S. resided at Geneva, making frequent visits to Pescia and England. His latter days were, however, darkened by the troubles of his native city, in whose politics he took a keen interest. He died 25th June 1842. S. has contributed more to historical literature than any other writer of his time, and the labour which he bestowed on his works has never been surpassed. 'Nine times,' he says, 'have I traversed Italy, and I have visited every place which has been the scene of any great historical event.' For twenty years he worked habitually eight hours a day. Both as a worker and as a thinker, he was thoroughly conscientious. His mind was to the last open to truth; neither fettered by prejudice nor blinded by self-conceit. At the same time, no one has surpassed him in tenacity of purpose, nor in energy in following it out. His feelings on religious questions were especially intense. Having on one occasion heard a sermon in an English church on eternal punishment, he vowed never again to enter another church holding the same creed; and 'never to contribute to spread what the English call their Reformation; for, by its side Romanism is a religion of mercy and peace.' His private character was singularly amiable and benevolent. His whole career is a noble one, full of interest and instruction.—See *Quarterly Review*, September 1843; *Vie et Travaux de Sismondi* (Paris, 1845); see also his Correspondence with Mademoiselle de St Aulaire (Paris, 1863); and his *Letters Inédites à Madame d'Albany* (1864).

SISTERS OF CHARITY. See BROTHERS AND SISTERS OF CHARITY.

SISTO'VA, an important commercial town of Turkey, in the eyalet of Widin, on the south bank of the Danube, about 35 miles up the river from Rustchuk. It has several mosques, an ancient and strong castle, where the 'peace of Sistova' between Austria and Turkey was concluded in 1791; manufactures cottons and leather, and carries on an active river-trade. Pop. about 20,000.

S'ISUPÂLA is in Hindu legend the sovereign of Chedi, a country situated in Central India, who was the enemy of Krishn'a (q. v.), and ultimately was slain by him. The history of this enmity, and the death of S., are the subject of the *S'is'upâlabadha* of Mâgha. See SANSCRIT LITERATURE.

SI'SYPHUS, a personage of Greek mythology, whom later accounts make to be the father of Odysseus. He is said to have been founder and king of Ephyra—afterwards Corinth—and both he and his whole house were notorious for their wickedness. He is, however, best known for the punishment which he suffered in the lower world, either for treachery towards the gods, or for his wholesale robbery of travellers, whom, at the same time, he murdered with a huge block of stone. He was condemned to roll an immense boulder from the bottom to the summit of a hill, which, whenever it reached the top, rolled down again, and the task of S. had to be begun anew.

SÎTÂ is, in Hindu Mythology, the daughter of Janaka, a king of Mithilâ, and the wife of Rama. See VISHN'U. The word means literally 'furrow,' as she was not born in the usual sense of this word, but arose from a furrow when her father was ploughing the ground, whence she is also called *Pârthivî* (from *pr'thivi*, the earth). Her history is related in the RÂMÂYAN'A (q. v.).

SITKA, or NEW ARCHANGEL, the principal settlement in the Territory of Alaska, is a small place of about 2000 inhabitants, on the west coast of the island of Sitka or Baranov, the largest island in the group known as George III.'s Archipelago. Lat. 57° 3′ N., long. 135° 18′ W. S. was formerly the residence of the governor of Russian America, and has a magnetic observatory. Here the chief establishments of the Russian-American Company, incorporated 1799, for fishing and hunting fur-bearing animals, were situated. The Company employed 50 ships, and about 850 men, but their privileges expired in 1863.

SITOPHO'BIA, or SITOMA'NIA. The repugnance to or refusal of food may range from mere impairment or loss of appetite, or hysterical antipathy to particular viands, to total and prolonged abstinence, as a symptom of delusion or delirium. In the insane, food has been consistently refused for years. During this time, the system was, of course (see FASTING), sustained by compulsory alimentation. The causes of such a course are generally local disease in the organs of digestion, creating disgust and loathing towards food, and associating suffering with the process of nourishment; the fear of death, or the desire for death. The motives assigned for such feelings or resolution vary, of course, as the morbid condition may affect the stomach or the brain; and, according to the mental state predominating, suicide may be courted, or poisoning, drugging, or pollution of aliment may be dreaded. The throat or bowels may be imagined to be hermetically sealed; God or Satan may have imposed abstinence; the body is dead, inanimate, or belongs to another. Absurd as such principles of action may be, they prove inexpugnable to persuasion, or to the pangs of hunger and exhaustion, and require a special course of treatment. The determination may be exorcised by medicine; it may be overcome by commands, threats, bribes; it may be evaded by giving eggs, cocoa-nuts, milk from the cow, and other substances, into which mercury, arsenic, &c., cannot well be introduced; or it may be defeated by placing food in the stomach through the instrumentality of the stomach-pump. There have been epidemics of maniacal abstinence.—Chipley, *American Journal of Insanity*, July 1859; Browne, *Report Crichton Institution*, 1854.

SI'TTA. See NUT-HATCH.

S'IVA (a Sanscrit word, literally meaning happy, auspicious) is the name of the third god of the Hindu Trimûrti (q. v.) or triad, in which he represents the principle of destruction. The name S., as that of a deity, is unknown in the Vedic hymns, but established as such in the epic poems, *Purân'as* and *Tantras*. The worshippers of S. (see S'AIVAS) assign to him the first place in the Trimûrti; and to them he is not only the chief deity, but the deity which comprises in itself all other deities. Thus, in the *S'iva-Purân'a* (see PURÂN'A), he is addressed as Brahma, Vishn'u, Indra, Varun'a, as the sun and the moon, as earth, fire, water, wind, &c.; but even in the Purân'as relating to Vishn'u, his power is exalted in praise, and he is addressed with the utmost awe. The symbol of S. is the *Linga* (q. v.), emblematic of creation, which follows destruction. From each of his numerous attributes or characteristics he derives a name or epithet. He has five heads (hence his name *Panchânana*, &c., the five-faced); three eyes (hence his name *Trinetra*, &c., the three-eyed), one of which is on his forehead, and indicates his power of contemplation; and in the middle of his forehead he wears a crescent. His hair is clotted together, and brought over the head so as to project like a horn from the forehead. On his head he carries the Ganges, whose course he intercepted by his hair, when

this river descended from heaven, so as to enable the earth to bear its fall (hence his name *Gangâdhara*, &c., the Ganges-bearer). Round his neck he carries a garland of human skulls; and his throat is dark blue, from the poison which he swallowed when it emerged from the ocean, churned by the gods for the attainment of the beverage of immortality, and threatened to destroy the world. In his hands he holds the trident, a club or pole, armed at the upper end with transverse pieces, representing the breastbone and ribs adjoining, and surmounted by a skull and one or two human heads. His weapons are the *Khinkhira*, which is not described, a bow called *Ajakava*, or *Ajagava*, a thunderbolt, and an axe. As the destroyer of the world, he is also called *Kâla* (Time or Death), and represented as of black colour. One of his representations is also half-male and half-female, emblematic of the indissoluble unity of the creative principle (hence his name *Ardhanârîs'a*, the half-female-lord). He is clothed in a deer-skin; or he also holds a deer in one of his hands; or he sits on a tiger-skin, or is clothed in it. When riding, his vehicle is the bull Nandi, whom he also carries as an emblem in his banner. He resides on the wonderful mount Kailâsa, the northern peak of the Himalaya, where he also rules over the north-east quarter. His principal wife is *Durgâ* or *Umâ* (q. v.); his sons are GANES'A and KÂRTTIKEYA (q. v.). One of his principal attendants is *Tan'du*, who is one of the original teachers of the arts of dancing and mimicry, whence S. is the patron of the dancers, and is called *Nat'es'wara* (lord of the dancers). Besides Tan'du, a host of other attendants and companions, together with demons and other beings surrounding him, are named by the Purân'as.

Amongst the principal achievements of this god is his conflict with the god Brahma, who was originally possessed of five heads, but lost one through exciting the anger of S.; for the fifth head of Brahma once disrespectfully addressing S., and even challenging his power, S. immediately cut off the offending member with the nail of his left thumb. A similar penalty he inflicted on *Daksha*, his father-in-law, who once performed a great sacrifice, but neither invited his daughter Satî nor her husband S'iva. S., nevertheless, appeared at the sacrifice; but when Satî, offended at the reception she met with, threw herself into the sacrificial flames, S. cut off the head of Daksha; and Daksha would have remained headless, had not the gods interfered in his favour with S., who, out of compassion, replaced his head by that of a ram. Besides these feats, he killed several demons—*Ruru*, *Andhaka*, *Tripura*; and he also reduced to ashes *Kâma* (the god of love), who, at the instigation of the gods, undertook to excite the desire of S. to procreate a son, but was indiscreet enough to choose for this purpose a time when S. was engaged in fierce austerities (see KÂMA). S. is especially worshipped under the symbol of the Linga; but there are periods at which homage is paid to him also under other forms, corresponding with the description given above. Hindu mythology knows, properly speaking, no incarnations of S. like those of Vishn'u; in some writings, however, some of his forms, especially that called Bhairava, and that called Vîrabhadra, are considered to be his sons or incarnations. S., like Vishn'u (q. v.), has a thousand names by which he is addressed; some derived from his exterior attributes have been mentioned before; among the rest, the principal are *Is'a* or *Is'wara* (lord); *Mahes'a* or *Mahes'wara* (the great lord); *S'ankara* (the conferrer of happiness; *Rudra* (the terrible) or *Mahârudra* (the very terrible); and *Mahâdeva* (the great god). For his worshippers, see S'AIVAS.

SI'VAS, a city of Asiatic Turkey, capital of the pashalic of the same name, is situated on the Kizil Irmak (anc. *Halys*), 60 miles south-south-east of Tokat. S. covers a large extent of ground, is well built, has numerous old mosques, khans, gardens, and excellent bazaars, manufactures coarse woollens, and carries on a considerable transit trade. Pop. 25,000, of whom about 5000 are Armenians, the rest Turks. S. is built on the site of the ancient *Sebasteia*, from which it derives its name.

SIVA'SH, or PUTRID SEA. See CRIMEA.

SIVATHE'RIUM (*Siva*, an Indian god; and Gr. *therion*, a wild beast), a remarkable genus of extinct mammals, found in the Miocene strata of the Sewalik Hills, in Northern India. It had a large skull, nearly as long as that of an elephant, supported on a neck little short of that of a giraffe, but much stronger. The face was short, and the nasal bones were prolonged into a pointed arch above the external nostrils, indicating the existence of a trunk or proboscis, an organ unknown among the Ruminantia to which it belonged. Like the existing 4-horned antelope of India, it had two small diverging horns, rising from the brow between the orbits, and two large, probably palmated horns, further back. In general appearance, it resembled a huge antelope. The remains of two species have been described by Falconer and Cautley.

SIX ARTICLES, STATUTE OF, an enactment of the 33d year of Henry VIII., passed June 7, 1541, and commonly called the Bloody Statute. The object of this statute was to compel, from all the subjects of the crown, the uniform profession of certain doctrines, six in number, which are carefully recited in the act. These doctrines are (1), the Real Presence of Christ in the Eucharist, and Transubstantiation; (2), the sufficiency of communion in one kind only; (3), the unlawfulness of the marriage of priests; (4), the obligation of vows of chastity; (5), the propriety of retaining private masses; (6), the expediency and necessity of auricular confession. The penalties of this act exceeded in severity almost every precedent, at least in England, and they are specially severe against impugners of the first article, all of whom, whether they dispute, write, or preach against it, are to suffer death as heretics, with forfeiture of all their goods to the crown, and without being allowed to abjure the error. With regard to the remaining four articles, the usual penalty of felony is attached to the crime of publicly preaching against them; private impugners are liable for the first offence to imprisonment at the king's pleasure, for the second, to death; and the same, or nearly the same penalties are enacted against priests or nuns marrying or cohabiting, and against persons contemptuously refusing to confess at the prescribed times, or to receive the sacraments. The act at first was enforced with great severity, but it was somewhat mitigated in 1544, and was finally repealed in 1549.

SIXTUS, the name of five popes, of whom two call for particular notice, Sixtus IV. and Sixtus V. The former (originally named Francesco della Rovere), born July 22, 1414, was a native of a small village near Savona, and a member of a very humble family. He was a scholar of the celebrated Cardinal Bessarion, and became a member of the Franciscan order, in which capacity he obtained the highest reputation throughout Italy as a preacher. On the death of Paul II. in 1471, Rovere was elected to the Roman see. The domestic government of S. has been strongly condemned. His inordinate partiality to his relatives exhausted

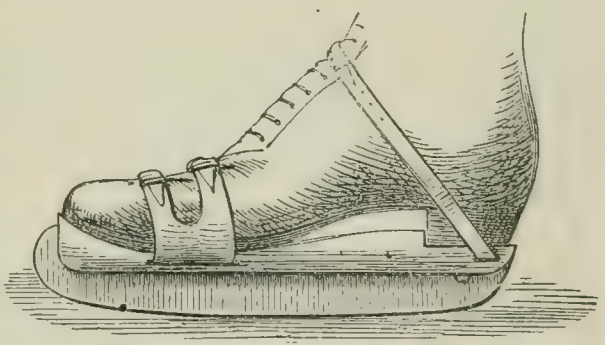
the papal treasury, and led to many questionable exactions, and to gross abuses in the dispensation of church patronage. His excessive facility, too, in dispensing favours, led to his not unfrequently conferring the same benefice on more than one individual. But the worst imputation upon the memory of his pontificate arises in connection with the political affairs of Florence, and especially with the conspiracy against the Medici family, known in history as the Pazzi conspiracy. In the last act of this nefarious plot, the murder of Giuliano in the church at Florence, S.'s nephew, Riasio, was present, and when, after its failure, the leaders, including the Archbishop of Pisa, were executed, S. excommunicated the Duke Lorenzo and all the magistrates of the city. Although this censure was passed professedly for the violation of the immunities of the church in putting an ecclesiastic to death, yet it has drawn upon S. the suspicion of complicity, or at least of connivance after the fact; and has led to much controversy among historians. The necessities of defence against the Turkish invasion embarrassed still further the finances of the pope, and even the Catholic historians deplore the lengths to which ecclesiastical exactions and the simoniacal distribution of benefices were carried in the latter years of Sixtus. In many respects, nevertheless, his administration was liberal and public spirited. He did much to foster learning and to encourage art. Under him, the Vatican library continued to increase, and he contributed notably to the improvement and decoration of the city. In 1482 he entered into an alliance with the Venetians against the Duke of Ferrara, which led to a general Italian war, and ended in a dissolution of the Venetian alliance, so mortifying to the pope, that his death is said to have been caused by chagrin and mortification, August 13, 1484.—Sixtus V., in many respects, one of the most remarkable of the modern occupants of the Roman see, originally named Felice Peretti, was born (December 13, 1521) near Montalto, of parents so poor, that his boyhood was spent in the humble occupation of a swineherd. While thus engaged, the boy attracted the notice of a conventual Franciscan father, who procured his admission into the order. He was ordained priest in 1545, and became professor of theology at Siena. His reputation as a preacher led to his being transferred to Rome, where he rose to its first dignities. He accompanied Cardinal Buoncompagno as theologian in his legative mission to Spain (1565); and on the accession of Pius V. to the pontificate, was named cardinal (1570). On the accession of his former patron, Buoncompagno, under the name of Gregory XIII., Cardinal Montalto might have exercised the highest influence, but he lived a retired and mortified life, and was believed to have fallen almost into the decrepitude of age and infirmity. This appearance was afterwards ascribed by his enemies to the design of concealing his ambitious views; and there is a well-known but apocryphal story of his having, when elected pope on the death of Gregory in 1585 (April 24), flung aside his crutch, and revealed himself to the astonished cardinals in the full vigour of his physical strength and his moral character. His pontificate, however, was a most active and energetic one, and was marked by vigorous measures of improvement in every department of administration, ecclesiastical as well as civil. His first care was to repress the prevailing licence and disorder of the city of Rome, and of the papal states generally, by effectually breaking up and exterminating the lawless bands of outlaws by which both were infested. His administration, both in this matter and in the repression of immorality, was rigorous perhaps to the extreme of cruelty; but the evil was one which seemed to call for extreme remedies. He reformed the administration of the law, and the disposal o public patronage; and he entered upon numerous and most comprehensive projects for the moral and material improvement of Rome. Many of his great works are still recognisable at Rome under his name, and are popularly remembered as his; among which are the library buildings of the Vatican. A distinguishing characteristic of his administration, too, was its disinterestedness. He steadfastly refused to use his position for the purpose of advancing any of his relatives, or to bestow upon them property or money derived from the public; and by judicious retrenchment he secured within the first years of his short pontificate a surplus of above 5,000,000 of crowns. It is of course impossible to enter into the details of his foreign policy; it will be enough to say that its great aim was, in the strongest sense of the words, to advance the cause of the Roman Catholic Church in every portion of Christendom, against the Huguenots in France, against the Lutherans in Germany, and against Queen Elizabeth in England. At the same time, he entertained a deep jealousy and apprehension of the designs of Spain; and he resisted persistently the excessively rigorous measures of the Spanish Inquisition as organised under Philip II. His church administration was equally vigorous and energetic. He fixed the number of the Sacred College of Cardinals at 70; and it was under him that the present organisation of separate congregations of cardinals for the several departments received some of its most important developments. He published a new edition of the Septuagint, and an edition of the Vulgate, which has become famous from the multiplicity of its errors, subsequently corrected in the edition of Clement VIII. Many of the popular stories regarding him are derived from Gregorio Lete's *Vita di Sisto V.* (2 vols., Lausanne, 1669), a work of no authority. See also Tempesti, *Storia della Vita e Gesti de Sisto V.* (2 vols., Rome, 1754); Lorentz, *Sixtus V. und seine Zeit* (Mainz, 1852); Ranke, *Fürste und Völker von Süd-Europa*, and Segretain, *Sixte V. et Henri IV.* (1861).

SI'ZAR (from *size*, in university slang, an allowance of victuals from the buttery—or the smallest quantity of anything which can be bought, a word derived from *assize*, formerly the same as *assess*, to apportion), a name given to an order of students at Cambridge and Dublin universities, who are admitted on easier terms than others. Duties of a somewhat menial kind were originally required to be performed by the sizars, but these have long since gone into disuse. Sizars are not on the foundation, and therefore so long as they remain such, are not eligible for fellowships; but they may at any time become pensioners, and generally sit for scholarships immediately before taking their first degree. If successful, they are on the foundation, and may become candidates for fellowships when they have taken their degree.—At Oxford, there is a similar order of students, denominated Servitors.

SIZE. See Glue and Gelatine.

SKA'GEN, Cape, or The Skaw, the most northerly point of Jutland, Denmark. On it is built a light-house of stone, 67 feet high, the lat. of which is 57° 43′ 8″ N., long. 10° 36′ 5″ E.; and near it is a small town of 1400 inhabitants.

SKA'GER-RACK ('Crooked Strait of Skagen; *rack* is probably from the same root as A.-S. *raca*, Ger. *rachen*, throat; thus being equivalent to the Celtic *Kyle* [in Kyles of Bute], Lat. *gula*, English *gully*—is the *Race* of Alderney allied to *Rack?*), an arm of the North Sea (q. v.) lying between Denmark and Norway, and communicating with the Cattegat, is about 150 miles long from



west-south-west to east-north-east, and 80 miles broad. The depth is much greater on the Norwegian than on the Danish coast, being on the former about 200 fathoms, while on the latter it varies from 30 to 40 fathoms, increasing towards the centre to about 60. When free from violent storms —to which, however, it is very subject—the current runs east on the side next Denmark, and west on that next Norway, the harbours being all on the latter coast.

SKALD (allied to *skill;* the radical sense is, to separate, and hence to discern) signifies, in old Norse, a poet. The name was given specially to that class of poets who exercised their art (*Skálld-skapr*) as a vocation requiring a learned education; that is, a knowledge of the construction of verse, and of the enigmatical imagery, roughly shaped out of obscure tradition, to which Scandinavian poets were prone. The great, if not the only, aim of the Skaldic poetry, was to celebrate the deeds of living warriors or of their ancestors. For this reason, princes attached Skalds to their courts, and competed with each other, by magnificent presents, for the possession of the most skilful minstrels. Very few complete Skaldic poems are extant; but, on the other hand, the multitude of fragments preserved, partly in the younger Edda (q. v.), partly in the Sagas (q. v.), and the Heimskringla (q. v.), is very great. A manuscript of the younger Edda, belonging to the university of Upsala (which has been printed in the *Historia Literaria Islandica* of Einarsen), contains a list of the most celebrated Icelandic and Norwegian Skalds of the 13th c., under the name of *Skálldatal.* The songs relating to the religious and heroic traditions of the North, which are found in the Edda, go back to an earlier time, in which the class or school of 'Skalds,' properly so called, did not yet exist. The authorship of these primitive Eddaic songs is unknown; but they are the sources from which the 'Skalds' of later times drew much of their inspiration.

SKA'LITZ, or SZAKO'LCZA, a town in the north-west of Hungary, near the borders of Moravia, 47 miles north of Presburg, on the left bank of the March, with a pop. of 8790. It is nearly in the form of a square, is surrounded by walls, has several Protestant and Roman Catholic churches, a Franciscan monastery, town-hall, &c., besides large manufactures of cloth. Good wine is produced in the vicinity, and hemp is largely grown.

SKATE, the popular name of several species of Ray (q. v.).—The COMMON S. (*Raia batis*), known in Scotland as the *Blue S.* or *Gray S.*, and in the south of England as the *Tinker*, is plentiful on most parts of the British coasts; the breadth of the body is to its length in the proportion of about four to three; the snout sharp; a slight concavity in the outline between the snout and the extreme lateral angle of the pectoral fin; a short hard tubercle in front of each eye, and another on the inner side of each; a single row of spines commencing on the dorsal ridge near the origin of the ventral fins, and reaching along the tail as far as the first of the two small fins which it bears; the upper parts grayish brown, the belly dusky white with darker lines. It attains a large size, having been known to weigh 200 lbs.—The LONG-NOSED S. (*R. rostrata* or *mucronata*) is remarkable for the elongation and sharpness of the snout. The upper surface is of a light lead colour, the lower grayish white. The tail has a row of crooked spines. This species is not uncommon on the British coasts, and attains a large size.—The SHARP-NOSED S. (*R. oxyrhynchus*) has also a very sharp snout, but less elongated. It is thicker in proportion to its other dimensions than any of the other British species, and attains a very great weight. The line of the body from the snout to the extreme lateral expansion is waved. The tail is armed with three rows of spines. The upper surface is of a brown colour; the colour being lighter than in the other species, this is generally known in Scotland as the *White Skate.*—The FLAPPER S. (*R. intermedia*) is very thin and broad; it has only a line of pointed tubercles on the tail; the upper surface is dark olive green, with numerous white spots. Skates are very voracious. They are often caught by lines, but the greater number of those brought to market are caught by trawl-nets. They are much esteemed for food in most countries, yet on some parts of the British coast they were until recently rejected as worthless.

SKATES AND SKATING. Skates are small keels or blades of iron or steel which are placed under the soles of the feet for the purpose of enabling the wearer to glide along the surface of ice. They are usually fitted to pieces of wood carved into somewhat of a boat-like form, to which straps of leather are adjusted, to enable the skater to attach them firmly to his feet. Of late, in some improved skates, the wood has given way to metallic fittings, which are neater, and perhaps preferable; they are, however, liable to rust, and consequently to get out of order. In Britain,

Skate attached to the Foot.

skating is a favourite pastime in winter; and in England and Scotland, and also in America, is carried to a degree of excellence not known in other countries: the skaters study the most graceful curves, and the utmost possible balancing of the body, when going at great speed. In such countries as Holland, and the more northern parts of Europe, skating is used merely as a necessary means of locomotion among the labouring classes, and its more ornamental manœuvres are rarely practised. It should always, if possible, be learned at an early age, as it is not acquired without some difficulty, and danger from falls. Within a few years skating-rinks have become very popular in the eastern United States, and thousands of both sexes meet on favourable lakes or streams, or prepared ice-surfaces, and perform graceful evolutions.

SKE'LETON (Gr. *skeletos*, dry) is the term applied in anatomy to designate the hard parts or framework of animals. In the invertebrate animals, the skeleton, except in the case of certain corals, is tegumentary or dermal, forming the outer hard and protective covering, as in the *Echinodermata*, *Mollusca*, and *Crustacea;* and like the epidermis and its appendages, is non-vascular, and can only be increased by additions to its edges. This hard insensible covering serves to protect the animal from hurtful external influences, and to afford fixed points of attachment to the muscles which move the body and limbs; the muscles, however, always lying interior to the skeleton, and not clothing it, as we see in the vertebrata. We scarcely ever observe, amongst the invertebrata, that

the skeleton bears any definite relation to the nervous system, which is merely protected by it to the same extent as the other soft tissues. Moreover, in none of these animals are the hard parts composed of true bone.

In the vertebrate animals, although we find occasional cases of bone being deposited in various parts of the body, its most constant position is around the central masses of the nervous and vascular systems, with rays extending thence into the middle of the chief muscular masses, forming the bases of the limbs. 'Portions of bone are also developed, to protect and otherwise subserve the organs of the senses, and in some species are found encasing mucus-ducts, and buried in the substance of certain viscera—as, e. g., the heart in the bullock and some other large quadrupeds. Strong membranes, called "aponeurotic," and certain leaders or tendons, become bony in some animals—as, e. g., the "tentorium" in the cat, the temporal fascia in the turtle, the leaders in the leg-muscles in the turkey, the nuchal ligament in the mole, and certain tendons in the abdominal muscles of the kangaroo, which, so ossified, are called the marsupial bones.'—Owen's *Structure of the Skeleton*, p. 163. In some animals (e. g., the sturgeon, the crocodile, the armadillo), bony matter accumulates upon or near to the surface of the body, rendering the skin in some cases absolutely ball-proof.

In order to give a clear conception of the osseous system, Professor Owen classifies its various parts according to their prevalent position. The superficial or skin bones constitute the 'dermo-skeleton' (Gr. *derma*, skin); the deep-seated bones, in relation to the nervous axis and locomotion, form the 'neuro-skeleton' (Gr. *neuron*, nerve); the bones connected with the sense-organs and viscera form the 'splanchno-skeleton' (Gr. *splanchnon*, a viscus or inward part); while those developed in tendons, ligaments, and aponeuroses are termed the 'sclero-skeleton' (Gr. *skleros*, hard). In the arrangement of the various parts of the dermo-, splanchno-, and sclero-skeletons, no definite plan or law can be detected. The definite end or purpose gained by the position of the bony plates, cases, or rods, belonging to these skeletons, is usually easily seen to be connected with the habits and well-being of the animals in which they occur, but the parts cannot be referred to one general type, as in the case of the neuro-skeleton. We will follow Professor Owen in taking the sturgeon and armadillo as examples of a dermo-skeleton, and shall condense the remarks which he makes on their outer covering. The head of the sturgeon is defended by a case of superficial bony plates, and the body by five longitudinal rows of similar plates, one extending along the mid-line of the back, one along each side of the body, and two along the belly, between the ventral and pectoral fins. These fishes habitually swim low and grovel along the bottom, turning up the mud and sand with their pig-like snout, and feeding on the decomposing organic substances carried down by strong and rapid currents. The heavy dermal osseous plates, regularly arranged in orderly rows along the middle and sides of the body, act as well-arranged ballast. The protection which their plate-armour affords them against the logs and stones hurried along their feeding-grounds, renders needless the ossification of the immediate case of the brain and spinal marrow, and, consequently, all the parts of the neuro-skeleton remain in the flexible, elastic, gristly state common to all the so-called cartilaginous fishes; the weight of the dermo-skeleton requiring that the neuro-skeleton shall be as light as possible, consistently with the defensive and sustaining functions which it is called to perform. The coat of mail in which the ganoid fishes of an early period were clothed, was probably subservient to the same ends as the dermal plates of the sturgeon; and in most of these fishes, as in the sturgeon, the dermal bones are coated externally with a very hard material resembling enamel. In these extinct fishes, the plates are more close-set than in the sturgeon, overlapping each other, and being fastened together like tiles by a peg of one entering a socket in the next, and conversely.

In the armadillo, the dermal bones are small, usually five or six sided, smooth internally, and variously sculptured externally—the pattern, however, being constant in, and characteristic of, each species. They are united together at their margins by rough surfaces, and collectively resemble a tesselated pavement. To allow of the requisite movements of the trunk of the armadillos, which have the power of rolling themselves into a ball, a certain number of transverse rows, marked in the figure, are interposed, having an elastic yielding attachment with one another, and with the anterior and posterior fixed parts of the trunk-armour; and by this arrangement, the head and limbs can be withdrawn beneath the central case, by the action of strong subcutaneous muscles. In the colossal extinct armadillo (the *Glyptodon*), the trunk-armour was not divided by bands, but was composed of one immovable piece, covering the back and sides—an arrangement by which the dermo-skeleton would afford increased protection against falling timber, the attacks of other animals, &c.

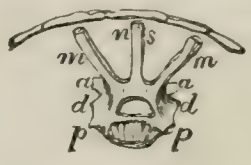


Fig. 1.—Transverse Section, shewing portions of Dermo- and Neuro-skeleton of Armadillo.
(The signification of the letters is subsequently given.)

The splanchno-skeleton is at first sight less apparent than the dermo-skeleton. In most air-breathing vertebrates, the larynx, trachea, and bronchial tubes contain a cartilaginous framework, which sometimes becomes ossified; in fishes, and in the batrachians in the tadpole state, the gills are supported upon a cartilaginous or osseous framework, developed independently of the vertebral skeleton; and in many mammals, the heart contains a bone that serves as a support for its muscular and ligamentous fibres. If to these parts we add the so-called 'sense-capsules'—the bony cap which is found in the outer coat of the eye in many birds and most fishes; the hard bony envelope which surrounds the internal ear, and which subsequently, as the petrous portion of the temporal bone, becomes incorporated in most vertebrates with the neuro-skeleton; and the turbinate bones of the nose—and the teeth, we have the principal parts of the splanchno-skeleton. The sclero-skeleton requires no further explanation than that which has been already given; and we therefore proceed to what may be called the skeleton proper—the neuro-skeleton.

From the nature of the subject, it is impossible to avoid the introduction of a considerable number of technical terms, which will probably be new, and will sound somewhat harshly to many of our readers; and as few writers can popularise a difficult subject more successfully than Professor Owen himself (unquestionably the greatest osteologist of the present age), we shall for the most part follow the history of the neuro-skeleton which he drew up for the benefit of general readers in *The Circle of the Sciences*. A thoughtful examination of the skeleton of any vertebrate shews that it is arranged in a series of segments, following and

articulating with each other in the direction of the axis of the body, from before backwards in brutes, from above downwards in man. Each complete segment, called a 'vertebra,' consists of a series of osseous pieces arranged according to the plan shewn in figs. 2 and 3, so as to form a bony hoop or arch above a central piece, for the protection of a segment of the nervous axis; and a bony hoop or arch beneath the central piece, for the protection of a segment of the vascular system. The upper hoop, N, is called the 'neural arch' (Gr. *neuron*, a nerve), and the lower hoop, H, the 'hæmal arch' (Gr. *hæma*, blood); while their common centre, C, is termed the centrum. The neural arch is formed by a pair of bones, *n*, *n*, called 'neurapophyses' (Gr. *apophysis*, a projecting part or process), and by a bone, *ns*, sometimes cleft or bifid, called the 'neural spine;' it also sometimes includes a pair of bones, *d*, *d*, called 'diapophyses' (Gr. *dia*, across). The hæmal arch is formed by a pair of bones, *pl*, called 'pleurapophyses' (Gr. *pleuron*, a rib); by a second pair, *h*, called 'hæmapophyses;' and by a bone, *hs*, sometimes bifid, called the 'hæmal spine.' It also sometimes includes parts or bones called 'parapophyses' (Gr. *para*, transverse). Bones, moreover, are developed, which diverge as rays from one or more parts of a vertebra. Professor Owen divides the various parts of a vertebra into (1) the autogenous and (2) the exogenous parts. The autogenous parts are those which are developed from independent centres of Ossification (q. v.), and are termed the elements of the vertebra; while the exogenous parts are those that grow from parts previously ossified, and are termed processes. The line between these two sets of parts cannot be strictly drawn, since parts which are usually exogenous are sometimes autogenous, and *vice versâ*. The autogenous parts or elements are the centrum, C; the neurapophyses, *n*, *n*; the neural spine, *ns*; the pleurapophyses, *pl*, *pl*; the hæmapophyses, *h*, *h*, and the hæmal spine, *hs*; while the exogenous parts or processes are the diapophyses (fig. 3), *d*, *d*; the parapophyses (fig. 5), *p*, *p*; the zygapophyses (fig. 3), *z*, *z* (Gr. *zygos*, a junction); the anapophyses (fig. 1), *a*, *a* (Gr. *ana*, backwards); the metapophyses (fig. 1), *m*, *m* (Gr. *meta*, between); the hypapophysis (fig. 5), *y* (Gr. *hypo*, below); and the epapophysis (fig. 2), *e* (Gr. *epi*, upon). These individual parts may be united with each other in various ways, and may occur in various degrees of development; sometimes they (or some of them) remain entirely disjoined even in the adult animal, while in other cases they are united into a single piece, so that their real distinctness can only be recognised by tracing the history of their development. In most instances, some one or more of these parts will be found to be altogether deficient, while in other cases one set of parts is exaggerated to a great degree. Thus, in fig. 4, which exhibits the third or parietal segment of the human skeleton, the neural arch, N, is much expanded, while the hæmal one, H, is contracted; while more commonly, as is shewn in fig. 5, which represents a thoracic segment or vertebra of a raven, the hæmal arch, H, is much expanded, and the neural one, N, contracted; while sometimes, again, as in the tail of the crocodile and of many other animals, both neural and hæmal arches are simultaneously contracted. The segments are commonly simplified, and made smaller as they approach the end of the vertebral column or axis, one element or process after another being removed until the vertebra is reduced to its centrum, as in the diagram of the archetype vertebral skeleton. If we glance at the typical vertebra represented in fig. 3, we observe the diapophyses projecting above a canal that serves for the passage of a blood-vessel, and parapophyses which form the lower boundaries of this canal. These elements never attain any high development in mammals, birds, or reptiles; thus, in the human cervical vertebra, they form the two roots of the transverse process surrounding the foramen for the passage of the vertebral artery, while in the thoracic vertebra of the bird (see fig. 5) the diapophyses, *d*, *d*, form the transverse processes, and the parapophyses, *p*, *p*, reduced to mere rudiments, form the articular

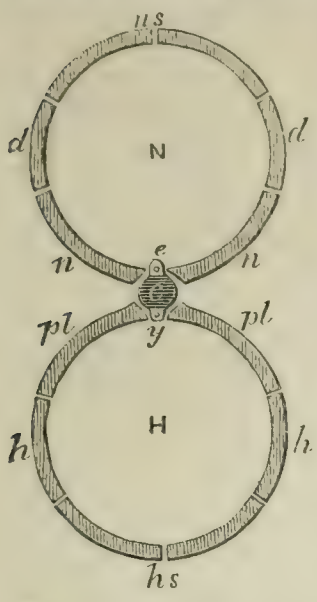

Fig. 2.—Typical Vertebra (ideal).

(The signification of the letters is fully given in the text.)

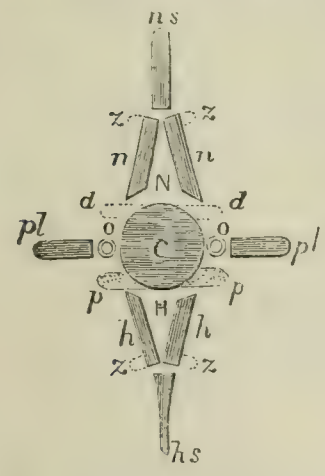

Fig. 3.—Another Modification of a Typical Vertebra:

C the centrum, giving off *d*, *d*, the diapophyses, and *p*, *p*, the parapophyses; the neural arch N, enclosing the spinal cord, is formed by *n*, *n*, the neurapophyses, and *ns*, the neural spine; the hæmal arch H, enclosing the great centres of the circulation, is formed by *h*, *h*, the hæmapophyses, and *hs*, the hæmal spine. From both the neurapophyses and the hæmapophyses may be given off the zygapophyses, *z*, *z*. The lateral arches which may enclose the vertebral arteries, O, O, are completed by the pleurapophyses, *pl*.

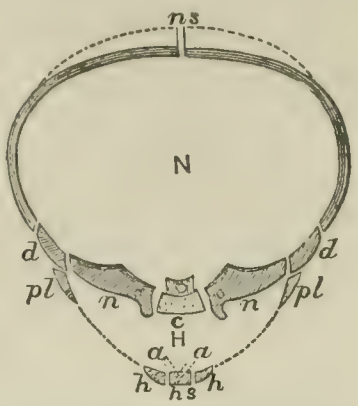

Fig. 4.—Parietal, or Third Segment or Vertebra of the Human Skeleton.

(Letters as in preceding diagrams.)

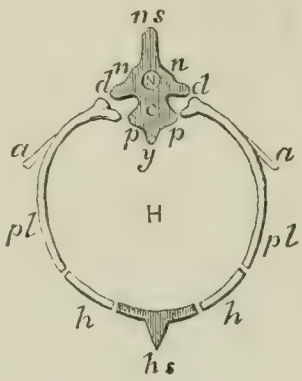

Fig. 5.—Thoracic Segment or Vertebra of a Raven.

(In this and the preceding figure, *a*, *a* are diverging appendages.)

surfaces with which the heads of the ribs come in contact. In fishes, however, they are much developed, and in the cod tribe are even larger and broader than the pleurapophyses or true ribs. The ordinary function of these lateral processes is to afford attachment to muscles, to protect the lateral vascular trunks (as in the case of the vertebral artery), and to give support to the pleurapophyses, *pl*, *pl*, whose development varies extremely in different parts of the same vertebral column, as well as in different animals. Then, in the human cervical vertebra (fig. 6), they form the short bifid transverse processes which are anchylosed at their base to the diapophyses and parapophyses which surround the vertebral canal. In the thoracic segments (fig. 5), they are developed separately, and

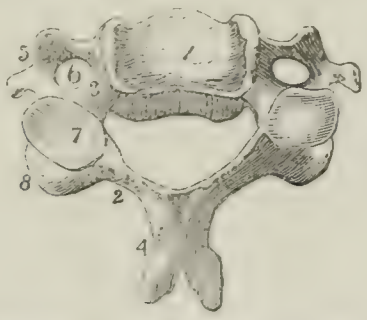

Fig. 6.—A Central Cervical Vertebra as seen from above:

1, the body; 2, the lamina; 3, the pedicle; 4, the bifid spinous process; 6, the vertebral foramen; 7, the superior articular process. This figure, as compared with the preceding ones, must be regarded as inverted, the neural arch being here below the centrum.

constitute the ribs which form the greater part of the circumference of the hæmal arch. Proceeding to the consideration of the parts below the centrum, we often find the entire hæmal arch wanting, as in the cervical and lumbar vertebræ of man and mammals; but in the tail of some mammals and of reptiles, a hæmal arch, protecting the caudal artery and vein, and closely resembling a neural arch, is found. It is in the thoracic region of mammals, birds, and reptiles that we find the greatest expansion of the hæmal arch (see fig. 5); the hæmapophyses here articulating with the extremities of the ribs instead of with the centrum, and the arch surrounding the entire visceral cavity. In man and mammals, the hæmapophyses remain unossified, and are known as the cartilages of the ribs; but in birds and reptiles, they are ossified, and constitute the sternal ribs. The hæmal spine, *hs*, presents great variety of form, and is often altogether absent. In the mammalian thorax, it occurs as a flat sternum; in birds, the flatness is replaced by a prominent keel on the mesial line, so that a transverse section almost resembles a neural spine; while in reptiles, again, the hæmal spine or sternum is flattened laterally, as in mammals. The hæmapophyses and hæmal spine are absent in the abdominal region of mammals and birds, but are continued backwards in the saurians or lizard-like reptiles, whose hæmal arch is, notwithstanding, incomplete, from the absence of pleurapophyses. In serpents, the hæmal arches are wanting through the whole trunk, the ends of the ribs being free; and in fishes generally, the hæmapophyses and hæmal spine are absent, or unossified.

Having noticed, as fully as our space permits, the modifications which the typical vertebra undergoes in various animals, and in different parts of the same animal, we now come to the more difficult subject of 'the archetype vertebrate skeleton,' which is made up of a series of vertebræ arranged in a continuous row. The accompanying scheme or diagram represents Professor Owen's conception of the common pattern or archetype of the vertebrate skeleton. It is difficult at first sight to see any resemblance between this figure and the human skeleton; but, in fact, the human skeleton, of all

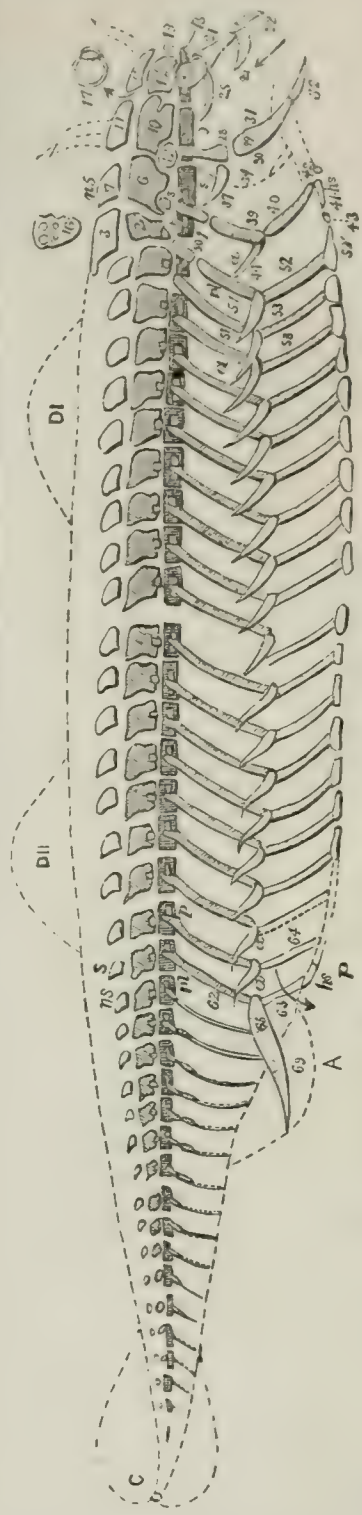

Fig. 7.—Diagram of Archetype Vertebrate Skeleton, composed of the following parts:

1, Basiocciptal; 2, Exoccipital; 3, Supraoccipital; 4, Paroccipital, constituting the neural arch of the first or occipital vertebra of the head (the epencephalic arch); 5, Basisphenoid; 6, Alisphenoid; 7, Parietal; 8, Mastoid, constituting the neural arch of the second or parietal vertebra (the mesencephalic arch); 9, Presphenoid; 10, Orbitosphenoid; 11, Frontal; 12, Post-frontal, constituting the neural arch of the third or frontal vertebra (the prosencephalic arch); 13, Vomer; 14, Prefrontals; 15, Nasal, constituting the neural arch of the fourth or nasal vertebra (the rhinencephalic arch); 16, Petrosal or acoustic sense-capsule; 17, Sclerotic, or ophthalmic sense-capsule; 19, Ethmo-turbinal, or olfactive sense-capsule; —20, Palatine; 21, Maxillary; 22, Premaxillary, constituting the maxillary hæmal arch; 25, 27, being its diverging appendages; —28, Tympanic; 29—32, Mandibular or lower jaw, constituting the mandibular hæmal arch; 34, 37, Opercular, being the diverging appendages of this arch;—38, Stylohyal; 39, Epihyal; 40, Ceratohyal; 41, Basihyal; 42, Glossohyal; 43, Urohyal, constituting the hyoidean hæmal arch; 44, Branchiostegal, being its diverging appendages; 50, Supra-scapula; 51, Scapula; 52, Coracoid; 52, Episternum; 53, Anterior member, constituting the scapular hæmal arch, with its diverging appendages; 58, Clavicle;—62, Ilium; 63, Ischium; 64, Pubis, the hæmapophysis of one of the lumbar vertebræ; 65, 69, Posterior extremity, constituting the hæmal arch of the sacral vertebra skeleton, with its diverging appendages.

others, recedes the furthest from the common pattern; and if we turn to fishes, which were the first form of vertebrate life introduced into this planet, we find that they deviate the least from the archetypal idea. If proof be demanded that a given bone in the human skull is an element of a particular vertebra, it is afforded by tracing the same bone through its various modifications in mammals, birds, reptiles, and fishes, till the simple archetypal form is arrived at. The skull is found to be but a continuation of the backbone, and to consist of four vertebræ or segments, corresponding to the four consecutive enlargements of the nervous system which we call the brain. These segments, reckoning them

from behind forwards, are termed the occipital, the parietal, the frontal, and the nasal segment. Each segment consists of a neural and a hæmal arch.

The Neural Arches are:

N. I. Epencephalic Arch (bones Nos. 1, 2, 3, 4 in figure). N. II. Mesencephalic Arch (bones Nos. 5, 6, 7, 8 in figure). N. III. Prosencephalic Arch (bones Nos. 9, 10, 11, 12 in figure). N. IV. Rhinencephalic Arch (bones Nos. 13, 14, 15 in figure).

The Hæmal Arches are:

H. I. Scapular Arch (Nos. 50—52). H. II. Hyoidean Arch (Nos. 38—43). H. III. Mandibular Arch (Nos. 28—32). H. IV. Maxillary Arch (Nos. 20—22).

The jaws are the modified hæmal arches of the first two segments; and the mouth opens at the interspace between these arches. The position of the vent varies (in fishes), but always opens behind the pelvic arch, S 62, 63, *p*, where this is ossified. Outlines of the chief ossified developments of the dermo-skeleton, in different vertebrates, are added by Professor Owen to the neuro-skeletal archetype; as, for example, the median horn, supported by the nasal spine, 15, in the rhinoceros; the pair of lateral horns developed from the frontal spine, 11, in most ruminants; the median folds, DI, DII, above the neural spines, one or more in number, constituting the dorsal fin or fins in fishes and cetaceans, and the dorsal hump or humps in the buffaloes and camels; similar folds are sometimes developed at the end of the tail, constituting the caudal fin, C, and the anal fin or fins, A, of fishes.

It has been already remarked, that bones which diverge as rays are formed from one or more parts of a vertebra. These 'diverging appendages' are mainly connected with the hæmal arches, and those which especially concern us are the pectoral appendages of the scapular arch, which become developed into fore-limbs or arms (54—57, fig. 9), and the pelvic appendages which are attached to their supporting hæmal arch, 63, *hs*. If we examine the skull of a cod-fish, in which the bones have been arranged

7, appendage proceeding from the pleurapophysis of the first arch to that of the second, and corresponding to internal pterygoid plate in man.
8, centra.

A, nasal vertebra.
B, frontal vertebra.
C, parietal vertebra.
D, occipital vertebra.
E, supra-scapula.
F, scapula.
G, ulna.
H, carpus.
I, radius.
K, metacarpus.
L, phalanges.
M, scapular arch.
N, hyoidean arch.
O, inferior maxillary arch.
P, superior maxillary arch.

according to the segments or vertebræ to which they belong, we observe that the occipital vertebra has a widely expanded hæmal arch, consisting of three pairs of bones with diverging appendages. The special names given by Owen to the various elements of that hæmal arch, from above downwards, are 'suprascapular,' No. 50; 'scapula,' No. 51; 'coracoid,' No. 52. The scapular arch thus formed supports and protects the heart or centre of the hæmal system, and in most fishes supports the pectoral fin, while in other animals the appendage that here becomes a fin is modified into a fore-leg, a wing, an arm, and a hand. Some of the special names originally employed in human anatomy are retained and applied to like parts in the pectoral fin of the fish; but it will be observed that Professor Owen designates each bone not only by a name but by a numeral. Of the two flat bones connecting the fin with the coracoid, the upper one is the 'ulna,' No. 54; the lower one, the 'radius,' No. 55 the row of short bones joined with these are the 'carpals,' No. 56; beyond which are the metacarpals and phalanges. Ascending from fishes to reptiles, we find that, in the lower batrachia (as the *amphiuma*), the scapulæ are detached from the occiput, and that other important modifications have occurred. The coracoids, *h* 52, are well expanded, three segments of the diverging appendage, *a*, are ossified, and two of these segments are bifid, shewing a simple beginning of the radiating multiplication of parts. The first segment is the seat of these modifications, which have acquired for it the special name of 'humerus,' 53; the two divisions of the next segment of the appendage are called 'ulnar,' 54, and 'radius,' 55; the gristly mass, 56, is the carpus, and the two bony divisions are the digits or fingers, 57. We have here got so distinct a rudimentary arm, separated from the head, although, according to the views propounded in this article, an appendage of the occipital segment of the cranium, that it is unnecessary to trace the further modifications that ensue, which lead finally to the arm and hand of man. It is only necessary to remark, that in mammals, except amongst the non-placental orders, the coracoid bone is reduced to a mere rudiment, being known as a process of the scapula, and that its function—namely, that of keeping the shoulders apart—is performed by the clavicle, which, according to Owen, is the hæmapophysis (58) of the first cervical vertebra (see fig. 7). With regard to the pelvic arch, we have only space to add that it must be regarded as the hæmal arch of one or more of the pelvic vertebræ; and there is undoubted evidence to shew that the pelvic and scapular arches are constructed on the same plan; the 'ileum' answering to the scapula, the 'ischium' to the coracoid, and the 'pubis' to the clavicle; and the same remark applies to the pelvic and scapular appendages.

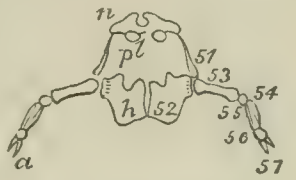

Fig. 9.—Posterior View of the Occipital Vertebra of *Amphiuma*:

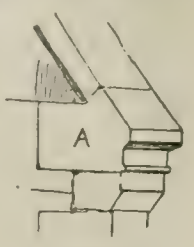
n, neurapophyses; *pl*, 51, pleurapophyses of occipital vertebra or scapula; *h*, 52, hæmapophyses of occipital vertebra, or coracoid bone; *a*, 53—57, diverging appendages of occipital vertebra, or anterior limbs.



'Of this,' says Mr Holden, probably our best authority on human osteology, 'a student may rest assured, that however minutely he may have scrutinised the bones, he cannot understand them unless he knows something of the "vertebrate archetype." Without this knowledge, he is like one who speaks a language fluently, but is ignorant of its grammar. The "archetype" may be said to be the grammar of all osteology.'

SKE'LLIGS, The, three rocky islands on the west coast of Ireland, about 8 miles west of Bolus Head, county Kerry, in long. 10° 32′ W. The lights on the Great Skellig are the first visible to ships crossing the Atlantic.

SKELTON, John, an early English satirical poet, is supposed to have been born about the year 1460, but whether in Norfolk or Cumberland, is uncertain. He studied at both Cambridge and Oxford, and received from each the academical honour of laureate. His sovereign, Henry VII., appointed him tutor to the young Prince Henry, afterwards King Henry VIII.; and Erasmus, in allusion to his learning, styled him the light and grace of British scholars. At this time, S. had produced some translations, written elegies on Edward IV. (1483) and the Duke of Northumberland (1489), and was author of some stiff court masques and allegorical poems of little or no merit. He entered the church in 1498, and became rector of Diss in Norfolk, shortly after which he seems to have struck into that vein of original vernacular poetry, addressed to the multitude, for which he is unique among our elder bards, and which helped to fix our language. It consists in a flow of rattling voluble verse, unrestrained satire and jocularity, and a profusion of grotesque imagery mixed up with Latin and slang phrases. At times, S. has gleams of bright fancy and snatches of pleasant description. Of this higher class is his *Philip Sparrow*, being a poetical lamentation made by a young maiden (whose charms the poet describes with great gusto and minuteness) over the loss of a pet bird slain in a convent of black nuns at Carowe near Norwich. The most humorous of his pictures of low life—often coarse enough—are found in the piece entitled *The Tunning* [or Brewing] *of Elynor Rummyng*, an alewife at Leatherhead in Surrey. This poem was highly popular, and was often reprinted in black-letter, garnished with a rude woodcut representation of the fat hostess. His best satires are *Colin Clout*, and *Why come ye not to Court?* The former is a general satire on the clergy; and the latter, a virulent attack on Cardinal Wolsey, whom the unscrupulous poet had previously flattered, but who had disappointed him of a prebend which he coveted. In this scurrilous lampoon, Wolsey is not only charged with arrogance, avariciousness, and incontinence, but is reminded of his 'base original' and 'greasy genealogy,' having been 'cast out of a butcher's stall.' The enraged cardinal ordered his libeller to be arrested, but S. took refuge in the sanctuary at Westminster, and received the protection of Abbot Islip. From this retreat he did not dare to emerge, but continued silent under its sacred shelter till his death in 1529. The 'pithy, pleasaunt, and profitable workes of Maister Skelton, Poete Laureate,' were collected and published in 1568, and reprinted in 1736. An edition, carefully edited by the Rev. A. Dyce, was issued in 1843, in 2 vols. 8vo.

SKE'RRIES, The (Skerry is a term for any isolated sea-girt rock), small islands about 2 miles off the north-west coast of Anglesey, having a light-house 117 feet high. See also Pentland Firth.

SKE'RRYVORE is the chief rock of a reef which lies about 10 miles south-south-west of the south-west point of the island of Tiree (q. v.), and 24 miles west of Iona. This reef, which stretches from 8 to 10 miles in a west-south-west direction, is composed of compact gneiss, worn smooth by the constant action of the waves, and was long a terror to mariners, having caused the loss of one ship annually for forty years previous to 1844. The Northern Light-house Commission had long intended the erection of a light-house on S., the only point of this dangerous reef which could afford the needful foundation; but the difficulty of landing on the rock, from the immense force (three tons to the superficial foot) with which the Atlantic waves beat upon it, caused the delay of the scheme till 1834, when preparations were made in earnest. The design and superintendence of the construction of the building were intrusted to Mr Alan Stevenson, who commenced operations on the rock in 1838, following generally the mode adopted by his father, Mr Robert Stevenson (q. v.), in the construction of the Bell Rock (q. v.) Light-house, and in spite of occasional disasters from tempests, completed his work in 1844. The light-house is 138½ feet high; at the base 42 feet, and at the top 16 feet in diameter. The light, a revolving one, is produced by the revolution of eight large annular lenses round a lamp of four wicks, according to Fresnel's first dioptric system, and can be seen at a distance of 18 miles. The cost of erection was close upon £87,000. S. Light-house is nearly ⅔ths higher than that on the Bell Rock, and more than twice as high as the Eddystone. A small group of rocks belonging to this reef, and situated three miles westward of the light-house, is known as Stevenson's rocks.

Skew.

SKEW, a sloping water-table—as on the set-off of a buttress, the cope of a gable, &c. This term is more generally used in Scotland than in England. The large stone (A) at bottom is called the skew-putt.

SKEW-BRIDGE, a bridge placed obliquely so as to cross a road or river at an angle not a right angle. Such bridges, built of stone, are not easy of construction, owing to the peculiar twisted forms which the voussoirs assume, and were scarcely ever used till the necessities of railway curves compelled their introduction. They are evidently a great improvement on the old-fashioned mode of twisting a road, first to the right, and then to the left, in order to get the bridge at right angles to the place to be crossed. Since the introduction of iron girders as the supports of bridges, skew-bridges have become easy of construction, and are now quite generally used.

SKIBBEREE'N, a market-town of the county of Cork, Ireland, and situated in lat. 51° 34′ N., long. 9° 16′ W., distant from Cork 52 miles south-west. It is a place of little commerce, and almost entirely without manufactures. The pop., in 1861, was 3694, of whom 3238 were Roman Catholics.

SKID, in Military and Naval Language, is any timber which is used as a base to keep one object from resting on another. Thus, a row of cannon in store will be kept from the ground by skids.

The term is also applied to the drag which is put on the wheels of carriages in going up hills, to prevent rolling backwards.

SKI'DDAW, a mountain in Cumberland, near the centre of the county; height, 3022 feet. A few miles to the south lie Derwent Water and the town of Keswick.

SKIN. Considered in its general physiological and histological (or textural) relations, the skin is merely a part of the great mucous system to which the mucous membrane and secreting glands also belong, and which consists of two essential elements—a *basement tissue*, composed of simple cutaneous membrane, and an *epithelium* of nucleated particles resting on it—while beneath the basement membrane are vessels, nerves, and connective tissue. See Epithelium and Mucous Membranes. In the skin, the hard and thick epithelium is termed *cuticle* or *epidermis*, and the true skin below it is termed the *derma* or *cutis vera*, and is chiefly formed of modified and very dense connective (or areolar or cellular) tissue.

The external surface of the skin formed by the cuticle is marked by furrows of different kinds. Some (termed furrows of motion) occur transversely in the neighbourhood of joints, on the side of flexion; others correspond to the insertion of cutaneous muscles; while others, of quite another kind, are seen in aged and emaciated persons, and after the subsidence of any great distention of the integument; and besides these coarse lines, most parts of the skin are grooved with very minute furrows, which assume various courses in relation to one another. These minute furrows are most distinctly seen on the palmar aspect of the hand and fingers, and on the sole of the foot. The outer surface of the skin also presents innumerable pores for the discharge of the contents of the sudoriparous and sebaceous follicles, or the sweat and fat glands; and the modifications of epidermis known as hair and nails occur on the same surface.

The deep layer of the skin consists of connective tissue, in which both the white and yellow fibrous elements are considerably modified as to the proportions in which they occur, and smooth muscles are present in no inconsiderable quantity in some parts of the skin. Where great extensibility, with elasticity, is required, the yellow (elastic) element predominates; and where strength and resistance are specially required, as in the sole of the foot, the *cutis* is chiefly composed of a dense interweaving of the white (inelastic) element. The thickness and strength of this layer differ greatly in different parts, according to the amount of resistance required against pressure. The skin is thicker on the hinder surface of the body than in front, and on the outer than on the inner sides of the limbs. 'It is unusually thin over the flexures of the joints. It is particularly delicate in the eyelids, and proportionably so in some other situations where great mobility is demanded. In regions which are most subject to external pressure, as the soles of the feet, it is firmly united by very dense laminæ to the subcutaneous fascia; and the intervals between these are provided with pellets of fat, forming a cushion, as an additional means of protection to the delicate organs it encloses and covers. Amongst the lower animals, we may notice numberless examples of an analogous kind.'—Todd and Bowman's *Physiological Anatomy and Physiology of Man*, vol. i. p. 407. The blubber of the whale merely represents, in a very exaggerated form, the layer of fat which generally occurs in the subcutaneous areolar tissue of man and most animals, serving as a soft bed on which the skin may rest, and gives the appearance of plumpness and symmetry to the outline of the body. It is on the external surface of the cutis that the *tactile papillæ*, or true organs of touch, are developed.

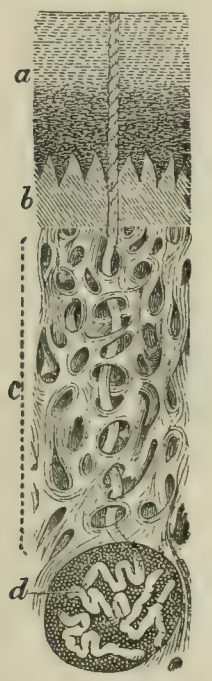


Fig. 1.—Vertical Section of the Skin of the Sole:

a, Cuticle; *b*, Papillary structure; *c*, *Cutis vera*, or true skin; *d*, Sweat-gland lying in a cavity on the deep surface of the skin, and imbedded in globules of fat. Its duct is seen passing to the surface. Magnified about 30 diameters.

Kölliker divides the true cutis into the 'reticular and 'papillary' portions, the latter being the reddish-gray external superficial layer which contains the upper portion of the hair follicles and cutaneous glands, and whose most important element is these tactile papillæ. They are most abundant and largest in the palm of the hand* and the sole of the foot, while in the back and in the outer sides of the limbs, they are almost entirely absent. They occur as small, semi-transparent, flexible elevations (see *b*, in fig. 1), which are usually conical or club-shaped in form; but in certain parts, as the palm of the hand, present numerous points (in which case they are termed compound papillæ).

The thickness of the true skin varies, according to Kölliker, from $\frac{1}{3}$th of a line to a line and a half. In its chemical characters, it agrees with those of the connective tissue, of which it is principally composed. The gelatine which it yields on boiling is derived mainly from the white fibrous tissue, and it is probably this element which is principally concerned in the changes which skin undergoes in the process of tanning. Arteries from the subcutaneous connective tissue freely enter into the structure of the skin, and are distributed to the fat-lobules, the sudoriparous and sebaceous glands (presently to be described),

trate the mode in which these capillaries are distributed over the fat-cells and in the papillæ. Those parts of the skin which border upon the epidermis are for the most part very freely provided with nerves, while in the deeper parts the

Fig. 4.—Arrangement of the Capillary Loops in the Skin.

nervous filaments are comparatively scanty. How they terminate, is still a subject of dispute; but the view most generally adopted is that they end in loops.

The glands occurring in the skin next claim our consideration. They are the *sudoriparous* or *sweat glands*, the *sebaceous* or *fat glands*, and the *ceruminous glands*. The *sweat-glands* exist in almost every part of the human skin. They lie in small pits in the deepest parts of the true skin, and sometimes entirely below the skin. Their orifices can be seen in the middle of the cross grooves that intersect the ridges of the papillæ on the hands and feet, their arrangement being here necessarily regular, while in other parts they are irregularly scattered. Their size and number in different regions of the skin correspond with the amount of perspiration yielded by each part; thus they are nowhere so much developed as in the axilla, or armpit. In that part of this region, which in the adult is more or less covered with hair, they form a layer of

a reddish colour, of about an eighth of an inch thick. They are soft, and more or less flattened by their pressure on one another, being imbedded in delicate connective tissue, and covered and permeated with a network of capillaries. On isolating one of these glands, and highly magnifying it, it is found to consist of a solitary tube, intricately ravelled, one end of which is closed, and hidden within the glandular mass, while the other emerges from the gland. The wall of the tube consists of an outer or *basement membrane*, with which the blood-vessels are in contact, and an *epithelium*, lining the interior, the former disappearing when the tube reaches the surface of the papillæ. The duct, on leaving the gland, follows a meandering and rather spiral direction through the reticular portion of the cutis to the interval between the papillæ, when it becomes straight; and it again assumes a spiral course in perforating the cuticle (see fig. 1). It is not easy to explain how or why so beautifully regular a spiral form should be given to the cuticular portion of the duct, which is rather wider than the rest, the average diameter of the duct being $\frac{1}{1700}$th of an inch.

The *sebaceous glands* are small whitish glands, which exist in almost every part of the skin, except the palms and soles, and are especially abundant in the scalp, face (the nose being particularly rich in

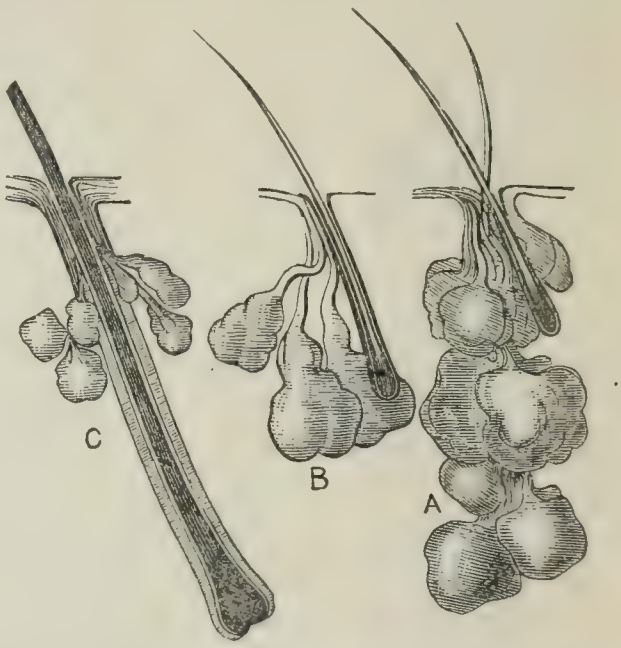

Fig. 7.—Sebaceous Glands, shewing their Size and relation to the Hair Follicles.

A and B, From the nose; C, From the Beard. Magnified 18 diameters.

(With two exceptions, the diagrams in this article are borrowed from Todd and Bowman.)

them), and about the anus. They are usually connected with the hairs, as shewn in fig. 7, and consist of a duct terminating in a blind pouch-like or pear-shaped extremity. The *basement membrane* of these glands is lined by an epithelium, in the particles of which are included granules of fatty or sebaceous matter, which, having become detached, constitutes the secretion. These glands are the seat .. the parasite known as *Acarus folliculorum*.

The *ceruminous glands* are brown simple glands, in external appearance like the sudoriparous glands, occurring in the cartilaginous portion of the external meatus of the ear. They yield an adhesive bitter secretion, which protects the membrane of the tympanum from the access of dust, insects, &c.

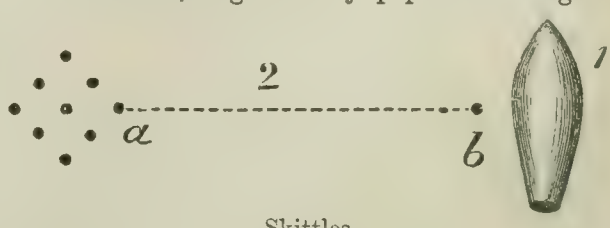
We shall conclude by taking a brief survey of the functions of the skin, omitting, however, its most important function, TOUCH (q. v.). Regarded as a protective covering, the skin possesses the combined

advantages of toughness, resistance, flexibility, and elasticity; the connective framework being the part which mainly confers these properties, although the epidermis co-operates with it. The subcutaneous layer of fat, and the modifications of epidermis in various forms, as hairs, wool, feathers, scales, &c., serve for the preservation of warmth, and occasionally (when they occur as claws, talons, &c.) as means of offence or defence. The skin is the seat of a twofold excretion—viz., of that formed by the sudoriparous glands, and that formed by the sebaceous glands. The fluid secreted by the sudoriparous glands is usually formed so gradually that the watery portions of it escape by evaporation as soon as it reaches the surface; but in certain conditions, as during strong exercise, or when the external heat is excessive, or in certain diseases, or when the evaporation is prevented by the application of a texture impermeable to air, as, for example, oiled silk, or the material known as mackintosh, or india-rubber cloth, the secretion, instead of evaporating, collects on the skin in the form of drops of fluid. When it is stated that the sweat contains urea, lactates, extractive matters, &c., and that the amount of watery vapour exhaled from the skin is, on an average, 2½ lbs. daily (according to Valentin's observation), the importance of the sudoriparous glands as organs of excretion will be at once manifest. Moreover, there is reason to believe, from the experiments of Scharling, Gerlach, and others, that the importance of the skin as a *respiratory* organ is far from inconsiderable, very appreciable quantities of carbonic acid being exhaled hourly by the external surface of the body. In the amphibia, in which the skin is thin and moist, the cutaneous respiration is extremely active; and that the respiratory function of the skin in the higher animals is also considerable, is proved not only by measuring the excreted carbonic acid, but by the fact, that if the skin is covered with an impermeable varnish, or if the body be enclosed, all but the head, in a caoutchouc dress, animals soon die, as if asphyxiated, their heart and lungs being gorged with blood, and their temperature before death gradually falling many degrees. The secretion of the sebaceous glands is a semi-fluid oily mass, which often solidifies into a white viscid tallow-like matter on the surface or in the glandular ducts, from which it can be removed by pressure, in a form resembling that of a small whitish worm or maggot. Under the microscope, cells containing fat, free fat mixed with epidermic scales, and sometimes crystals of cholesterin, are observed. Its chemical constituents, in addition to water, are a peculiar nitrogenous matter resembling casein, fat (consisting of palmitin and olein, soaps composed of palmitic and oleic acids), cholesterin, earthy phosphates, and chlorides and phosphates of the alkalies. Its purpose seems to be that of keeping the skin moist and supple, and by its oily nature, of hindering too rapid evaporation. Moreover, considered as an excretion, it must take a share in the purification of the blood.

The skin is, moreover, an organ of absorption: mercurial preparations, when rubbed into the skin, have the same action as when given internally. Potassio-tartrate of antimony, when rubbed into the skin in the form of ointment or solution, may excite vomiting, or an eruption extending over the whole body; and many other illustrations might be given. The effect of rubbing is probably to force the particles of the matter into the orifices of the glands, where they are more easily absorbed than they would be through the epidermis. It has been proved by the experiments of Madden, Berthold, and others, that the skin has the power of absorbing water, although to a less extent than occurs in thin-skinned animals, such as frogs and lizards. This fact has a practical application. In severe cases of dysphagia—difficult swallowing—when not even fluids can be taken into the stomach, immersion in a bath of warm water, or of milk and water, may assuage the thirst. Sailors, also, when destitute of fresh water, find their urgent thirst allayed by soaking their clothes in salt water, and wearing them in that state.

The *diseases* of the skin, and their classification into genera and species, have occupied the attention of many of the most eminent physicians during the last century; but none of the proposed classifications are very satisfactory. The more important affections are noticed in special articles.

SKIPS, large square baskets, lined with leather or skin, used in spinning-mills for carrying the bobbins of yarn; sometimes they are made entirely of thick hides. Wood or basket work would be apt to catch and break the delicate threads.



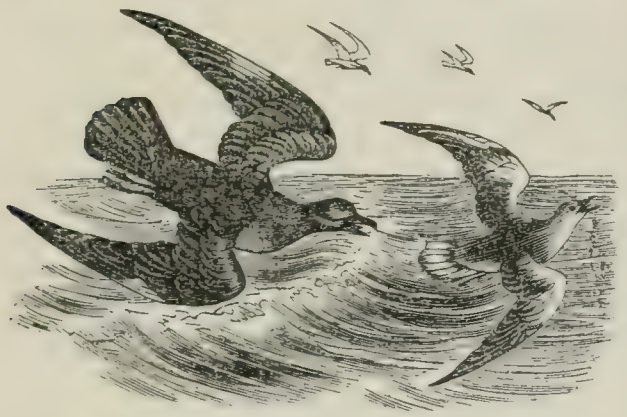
SKI'PTON, a market-town of England, county of York, is finely situated in a broad and fertile valley, near the river Aire, about 38 miles west of York, and 16 north-north-west of Bradford. S. carries on manufactures of cotton and woollen goods, and is a station on the Leeds and East Lancashire Railway. Pop. (1861) 4533.

SKI'RMISHERS are soldiers operating in loose array, two together—i. e., front and rear, with a lateral distance of about six paces between the files. When the army advances, the ground in front, and for some distance on each flank, is usually covered by skirmishers, to prevent surprise. If cavalry come suddenly on them, they rush together, and form small squares, called rallying squares. Skirmishers fire independently at their own discretion; but the rule is, that one of the two men composing a file should always have his rifle loaded. Orders are communicated by the sound of bugle.

SKI'RRET (*Sium Sisarum*), a perennial plant of the natural order *Umbelliferæ*, a native of China and Japan, but which has long been cultivated in gardens in Europe for the sake of its roots, which are tuberous and clustered, sometimes 6 inches long, and of the thickness of the finger. They are sweet, succulent, and nutritious, with a somewhat aromatic flavour, and when boiled, are a very agreeable article of food. A kind of spirituous liquor is sometimes made from them. Good sugar can also be extracted. S. was at one time more cultivated in Britain than it is at present, although there seems to be no good reason for its having fallen into disrepute. It is propagated either by seed or by very small offsets from the roots. It has a stem of 2—3 feet high; the lower leaves pinnate, with oblong serrated leaflets, and a heart-shaped terminal leaf, the upper ones ternate with lanceolate leaflets.

SKI'RTING, the board round the bottom of the walls of rooms. When large, it is called a base-plinth.

SKI'TTLES, a game very popular in England



Skittles.

amongst the frequenters of public-houses. It is usually played in a covered shed, called a skittle

alley, about 60 feet in length. The skittles are made of hard wood of the shape shewn in fig. 1, and they are placed upon the floor of the shed in the order shewn in fig. 2, *a*. The player, standing at *b*, throws a wooden ball, and tries to knock down the whole of the skittles in a given number of throws. The rules of the game vary in different places. The game is called 'Tenpins' in America, where the term *Skittles* is unknown.

SKOPI'N, a town of Russia, government of Riazan, and 160 miles south-east of Moscow, is situated on the Verda, a tributary of the Oka, which is itself a tributary of the Volga. It has manufactures of Russian leather, and a trade in corn and cattle. Pop. 8647.

SKU'A, or SKUA GULL (*Lestris*), a genus of birds of the family *Laridæ*, also known by the name JÄGER (Ger. hunter), and differing from the gulls in having the upper mandible more hooked at the tip, and the nostrils larger and further forward in the bill, the base of which is covered with a cere. The skuas are bold and powerful birds, and generally obtain their food by pursuing gulls or terns, and causing them to disgorge the fish which they have captured, which they dart upon and seize in the air. They also eat eggs and small birds. The COMMON S. (*L. cataractes*) is fully two feet in length,

Common Skua (*Lestris cataractes*), in pursuit of a Gull.

of a brown colour, with lighter streaks on the head and neck. It inhabits the northern seas, and breeds in some of the Shetland isles.

SKULL. The skull is divided into two parts, the cranium and the face. In human anatomy, it is customary to describe the former as consisting of eight, and the latter of fourteen bones; the eight cranial bones, which constitute the brain-case, being the *occipital, two parietal, frontal, two temporal, sphenoid*, and *ethmoid;* while the fourteen facial bones are the *two nasal, two superior maxillary, two lachrymal, two malar, two palate, two inferior turbinated, vomer*, and *inferior maxillary*. The bones of the ear, the teeth, and the Wormian bones are not included in this enumeration. The morphologist, however, who wishes to trace out the fundamental similarity of type in the structure of the various modifications of the vertebrate skull, will not be content with this arrangement, in which, as, for example, in the occipital, temporal, and sphenoid bones, the human anatomist considers as a single bone an osseous mass consisting primarily in man, and persistently in some of the lower vertebrates, of several distinct pieces or elements. Postponing to the close of this article any remarks on the structure of the vertebrate skull generally, we shall proceed to notice the ordinary anatomical relations of the human skull. The development of the skull is a subject of great interest, not only in itself, but as throwing light on many points which the study of the adult skull would fail to explain. At a very

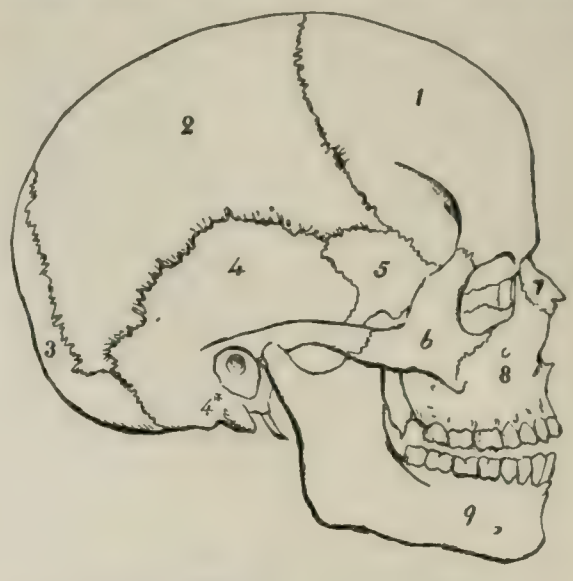


Fig. 1.—Side-view of Human Skull:

1, Frontal bone; 2, Parietal bone; 3, Occipital bone; 4, Temporal bone (squamous portion); 4*, Do. (mastoid portion); 5, Sphenoid bone; 6, Malar bone; 7, Nasal bone; 8, Superior maxillary or jaw bone; 9, Inferior maxillary or jaw bone.

early period of fœtal existence, the cerebrum is enclosed in a membranous capsule external to the dura mater, and in close contact with it. This is the first rudiment of the skull, the cerebral portion of which is consequently formed before there is any indication of a facial part. Soon, however, four or five processes jut from it on either side of the mesial line, which grow downwards, incline towards each other, and unite to form a series of inverted arches, from which the face is ultimately developed. Imperfect development or ossification of these rudimentary parts of the face gives rise to the peculiarities known as 'hare-lip' and 'cleft-palate,' or in very extreme cases to the form of monstrosity termed 'Cyclopean,' in which, from absence of the frontal processes, the two orbits form a single cavity, and the eyes are more or less blended in the mesial line.

The following is a brief summary of the succession of events that occur in the ordinary or normal development of the skull. Cartilage is formed at the base of the membranous capsule, which has been already described as thrown round the brain, and capable of enlarging with it. This is speedily followed by the deposition of ossific matter at various points of the capsule, which soon becomes converted into flakes of bone, which afford protection for the brain, while the intervening portions, which remain membranous, permit the skull to expand as its contents enlarge. The formation of these bony flakes on the convexity of the cranium is soon followed by the appearance of osseous nuclei in the cartilage at the base, corresponding to the future occipital and sphenoid bones. Lastly, the various bones, some originating in membrane, and some in cartilage (as described in the article OSSIFICATION), approach one another by gradual enlargement, and become united in various ways, so as to form a continuous, and ultimately an unyielding, bony case, which, in the words of Dr Humphry, 'is admirably adapted for the defence of the brain, for the accommodation of the organs of special sense, and for the attachment of the ligaments and muscles by which the skull is supported and moved on the spine.'—*The Human Skeleton*, p. 185. At the period of birth,

most of the principal bones have grown into apposition with their neighbours, forming the *Sutures* (q. v.), but one large vacuity remains at the meeting-point of the parietal and frontal bones, which is termed the anterior fontanelle,* which does not close

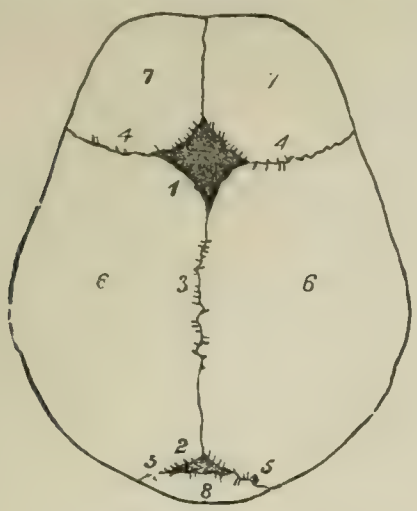

Fig. 2.

1, Anterior fontanelle; 2, Posterior fontanelle; 3, Sagitta suture; 4, 4, Coronal suture; 5, Lambdoidal suture. 6 6, Parietal bones; 7, 7, Two halves of the frontal bone, still ununited; 8, Occipital bone.

till the second year after birth, and sometimes remains open much longer. The deficiency of the osseous brain-case at this position not only facilitates the act of delivery, but also acts, according to Humphry, to some extent like a safety-valve during

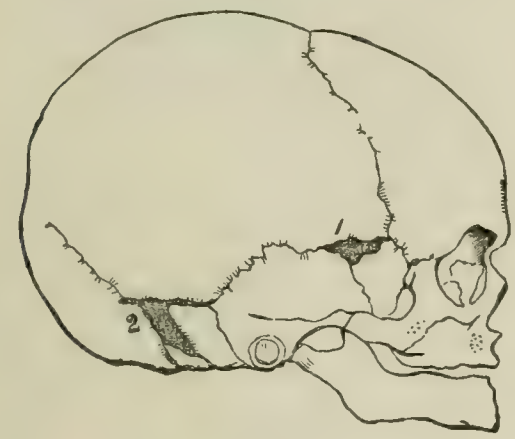

Fig. 3.

1, 2, Lateral fontanelles.

the first months of infantile life, at which time the brain bears an unusually large proportion to the rest of the body, and is liable to sudden variations of size from temporary congestion, sudden wasting of its substance, and other causes. The sutures remain distinct long after the closure of the fontanelles, and probably serve a purpose both in permitting an increase of the size of the cranium by the growth of the bones at their edges (although the enlargement of the cranial cavity does not entirely depend upon this growth at the edges), and in diminishing and dispersing vibrations from blows, and thus contributing to the security of the brain.

The number of centres of ossification in the skull is tolerably constant; each bone having a certain number. (Thus, the occipital has 7 centres, the temporal 5, the sphenoid 12, &c.; the total number being about 59.) In addition to these, centres frequently occur in the course of the sutures, giving rise to independent pieces, which are called the *ossa triquetra*, or the *Wormian bones*. They are regarded by Humphry as stop-gaps, developed in the membranous covering of the brain, when the extension of the regular osseous nuclei is likely, for some reason, to be insufficient to cover in the cranial cavity; and this view is supported by the observation that, in cases of rickets and hydrocephalus, the Wormian bones are especially abundant.

After the sutures have been formed, and the skull has acquired a certain thickness, a process of resorption commences in the interior of the bones, and reduces the originally dense structure to a more or less cellular or cancellated state. The interior thus altered is called the *Diplöe*, and by this change the weight of the skull is much diminished, while its strength is scarcely affected.

The diplöe usually begins to be apparent about the tenth year, and is most developed in those skulls which are thickest. Dr Humphry has observed it to be especially thick in idiots, and where the brain is small. 'Hence,' he observes, 'the propriety of the term *thick-headed*, as a synonym for *stupid*, derives some confirmation from anatomy.' A continuation of the same process of resorption, which causes the diplöe, gives rise to the formation of the cavities known as the frontal and sphenoid sinuses. The formation of the diplöe divides the walls of the cranium into three layers, viz., an outer tough layer; an inner dense, brittle, and somewhat glass-like layer, known as the vitreous table or layer; and the intervening cancellous diplöe. The vitreous table being more brittle than the outer layer, is apt to be fissured to a greater extent in fracture of the skull; and is even sometimes broken while the outer layer, which received the blow, has remained entire; although the diplöe must have great power in lessening the concussions transmitted from the outer to the inner layer of the skull. The growth of the skull after the seventh year proceeds slowly, but a slight increase goes on to about the age of twenty. The skull-bones are freely supplied with blood from arteries which pass from the dura mater internally and the pericranium externally, through the numerous foramina observed on both surfaces; the blood being returned by veins which take various directions.

The fact that concussion of the brain scarcely ever proves fatal, unless there is also fracture of the skull, affords the most distinct evidence that the skull is constructed in such a manner that so long as it maintains its integrity, it is able to protect its contents from serious lesion. This marvellous protective power is due to its rounded shape, whereby its strength is increased, and in consequence of which blows tend to glide off it, without doing material damage. Moreover, the curved lines or ridges which may be traced round the skull tend to strengthen it. The weakest part of the skull is at the base. Hence, notwithstanding its removal from exposure to direct injury and the protection afforded by the soft parts, fracture takes place more frequently at the base than at any other part of the skull, fracture often taking place here even when the skull was not broken at the part struck. There are two points in the architecture of the bones of the face which deserve especial notice, viz. (1), the great strength of the nasal arch, and (2) the immobility of the upper jaw, which is fixed by three buttresses, the nasal, the zygomatic, and the pterygoid.

* So called from the pulsations of the brain, which may be here seen resembling the rising of water at a spring or fountain. There are two fontanelles in the mesial line, as shewn in fig. 2, and two lateral fontanelles on either side, as shewn in fig. 3.

The base of the skull, whether seen from within or from below, presents many objects of physiological interest, in relation to the nervous system. As seen

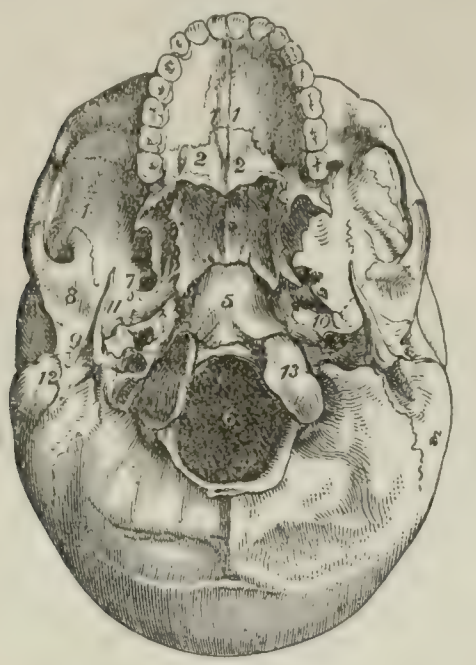

Fig. 4.

1, Hard palate, formed by the palate processes of the superior maxillary bone; 2, 2, Palate bones; 3, Vomer, dividing the openings of the posterior nostrils; 4. Zygomatic fossa; 5, Basilar process of the occipital bone; 6, Foramen magnum, through which the spinal cord passes; 7, Foramen ovale; 8, Glenoid fossa, in which the head of the lower jaw-bone lies; 9, External auditory foramen; 10, Carotid foramen of the left side; 11, Styloid process; 12, Mastoid process; 13, One of the condyles of the occipital bone.

from within, the base presents on each side three fossæ, corresponding to the anterior and middle lobes of the cerebrum and to the cerebellum. These fossæ are marked, as is the whole skull-cap, by the cerebral convolutions, and they contain numerous 'foramina' and 'fissures' which give passage to various sets of nerves and blood-vessels. The external or outer surface of the base of the skull, if we consider it from before backwards, is formed by the palate processes of the superior maxillary and palate bones; the vomer; the pterygoid and spinous processes of the sphenoid and part of its body; the under surface of the temporal bones, and by the occipital bone. The most important of the parts which it presents are named in the description of fig. 4.

The anterior region of the skull, which forms the face, is of an irregularly oval form, and the bones are so arranged as to enclose the cavities for the eyes, the nose, and the mouth, and to give strength to the apparatus for masticating the food. The size of the face and the capacity of the cranial cavity stand in an inverse ratio to one another, as may be readily seen by comparing vertical sections (through the mesial line) of human and other mammalian skulls; and if, in place of mammalian skulls, we take skulls of lower vertebrates (the crocodile, for example), this ratio is far more striking. In man, the face is at its *minimum* as compared with the cranial cavity, chiefly in consequence of the facial bones being arranged in a nearly vertical manner beneath the cranium, instead of projecting in front of it. The human face is also remarkable for its relatively great breadth, which allows the orbits for the reception of the eyes to be placed in front instead of on the sides of the head, and renders their inner walls nearly parallel. 'This parallelism,' says Dr Humphry, 'in man is associated with the parallelism of the optic axes, and contributes to that clear, accurate, and steady vision which results from the ready convergence of the eyes upon every object.' Each orbit is of a pyramidal form, with the apex behind, and is composed of seven bones—viz., the frontal, ethmoid, lachrymal, sphenoid, superior maxillary, malar, and palate, which last contributes very slightly to the human orbit, but is an important constituent in the orbit of many animals. The nasal cavities have been sufficiently described in the article Nose.

The different varieties of mankind present certain well-marked and characteristic peculiarities in the form of the skull. There are *three typical forms* of the skull which seem to be well established from the examination and comparison of a large number of crania—viz., the *prognathous*, the *pyramidal*, and the *oval* or *elliptical* cranium. When the upper jaw slopes forward, the insertion of the teeth, instead of being perpendicular, is oblique. A skull with this peculiarity is *prognathous* or *prognathic* (Gr. *pro*, forwards, and *gnathos*, a jaw); the opposite condition being termed *orthognathous* or *orthognathic* (Gr. *orthos*, upright). The Negro of the Guinea Coast and the Negrito of Australia present the prognathous character in its most marked form. The pyramidal form is characterised by the breadth and flatness of the face, which with the narrowness of the forehead, gives this shape to the head. The Mongolian and

Fig. 5.—Prognathous Skull of a Native Australian.

Esquimaux skulls belong to this type. The oval or elliptical type is that which is presented by the natives of Western or Southern Europe, and which is not distinguished by any particular feature so much as by the absence of the longitudinal projection of the first type, or the lateral projection of the second, and by a general symmetry of the whole configuration. The length of the skull, which to a great degree corresponds to the degree of development of the posterior cerebral lobes, has been taken by the late Professor Retzius as a basis of classification. He arranges all the varieties of mankind into two great classes—the *Dolichocephalæ*, or *long-heads*, whose cerebral lobes completely cover the cerebellum; and the *Brachycephalæ*, or *short-heads*, in whom the cerebral lobes do not extend so far. Each of these classes contains *orthognathous* and *prognathous* varieties. See Ethnology.

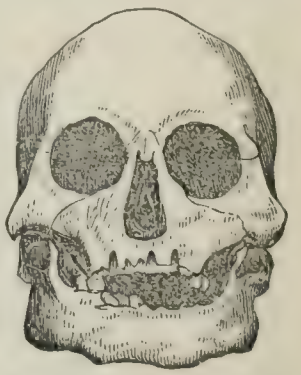

Fig. 6.—Pyramidal Skull of Mongolian Race.

It has been already stated in the article Skeleton that the skull is only the anterior prolongation of the backbone, and that it consists of four vertebræ or segments, corresponding to the four consecutive enlargements of the nervous system which ultimately

form the brain—viz., the *Rhinencephalon*, the *Prosencephalon*, the *Mesencephalon*, and the *Epencephalon*—embryonic segments giving rise to the nerves of smell, sight, taste, and hearing. These four vertebræ, taken from behind forwards, are termed the Occipital, the Parietal, the Frontal, and the Nasal vertebræ. For the anatomical evidence by which these cranial vertebræ are resolved into the essential elements of a vertebra, as described in the article SKELETON, we must refer to Professor Owen's various works on the Skeleton, or to the admirable summaries of them contained in Humphry *On the Human Skeleton* (for which we are indebted to many of the details introduced into this article), and to Holden's *Human Osteology*. There has been much discussion as to who originated 'The Theory of the Vertebrate Skull.' The claim undoubtedly rests between Goethe, the great poet, and Oken, one of the most original and distinguished comparative anatomists of the early part of the present century. We believe the truth to be that the idea of the true nature of the skull flashed across the poet's mind in 1790, but that nothing definite was published on the subject till 1807, when Oken independently arrived at and promulgated similar views. Our limited space has prevented us from noticing the skull of birds, reptiles, or fishes. On these subjects, the reader is referred to Huxley's *Lectures on Comparative Anatomy*, 1864, in which the structure and development of the human skull, as well as the skulls of all the lower vertebrate animals, are most copiously and philosophically discussed.

Fracture of the skull is an accident of such importance as to demand a special paragraph. As already remarked, fracture may take place either in the vault or at the base of the skull. We shall first consider *fractures of the vault*. Here the fracture is usually direct, the bone giving way at the point at which it was struck, and the result being either a simple fissure, or a breaking of the bone into several fragments (a comminuted fracture). Although fractures may be limited to the outer or to the inner surface of the skull, they most commonly extend through the whole thickness, and the broken bone is generally driven inwards; and the most ordinary form of fracture with depression is that in which several fragments of a somewhat triangular form have their points driven down and wedged into each other, while their bases remain on a level with the surrounding bone. There are no signs by which we can in all cases recognise the existence of fracture of the vault. 'Fissures,' says Mr Prescott Hewett, 'involving the whole thickness of the vault of the skull, constantly exist without ever having been suspected during life; and even an extensive and comminuted fracture, with great depression of the fragments, may, and often does, escape notice when the broken bone lies hidden under the temporal muscle, or under a large extravasation of blood.'—Holmes's *System of Surgery*, vol. ii. p. 116. When, however, the fracture is accompanied by a wound leading down to the bone, it may, in general, be easily detected. With regard to treatment, it is now an established rule, that simple fractures of the skull with depression, and without symptoms, are to be left alone. The depression may be so marked as to be easily detected; and yet so long as there are no symptoms, all operative interference, of whatsoever form, is carefully to be avoided.'—Prescott Hewett, *op. cit.* If, however, there be a wound leading down to the bone in a depressed fracture without symptoms, immediate operative interference is called for. When a depressed fracture is accompanied by primary brain-symptoms, an operation for the purpose of raising or removing the depressed fragments is usually necessary. If, however, the fracture is a simple one, and the symptoms are not urgent, milder remedial agents, as bleeding, purging, and low diet, may be first tried. Cases occasionally occur in which very urgent symptoms of cerebral pressure persist for a long time, and are relieved at once on the pressure being removed. A remarkable case is recorded by Cline (*Medico-Chir. Rev.*, vol. i. p. 471), in which a sailor remained in a state of unconsciousness for thirteen months in consequence of a wound causing fracture and depression of one of the parietal bones. Cline trepanned the part, and elevated the bone; and on the evening of the same day, the sailor sat up in bed, and though at first stupid and incoherent, soon became rational and well, upwards of a year having elapsed in which his life was a complete blank.

Fractures of the base may be direct or indirect, but in most cases are indirect, that is to say, the bones give way at a point remote from the seat of the blow, as has been already shewn. At certain parts, however, the bones of the base are so thin, that if direct pressure be brought to bear upon them, they readily give way. Thus, scissors, slate-pencils, tobacco-pipes, &c., have often been thrust into the skull through the orbits or the nostrils, and these wounds are very serious, from the readiness with which the brain may be thus injured. The only symptoms that can be depended upon as indicating a fracture of the base of the skull are connected either with an escape of the substance of the brain, or blood, or watery fluid, or with an injury done to the nerves as they emerge at the base. Out of 32 cases of fractured base observed by Hewett, bleeding from the mouth or nose occurred in 14, and bleeding from the ear in 15 cases. A copious watery discharge from the ear was, until very recently, regarded as a diagnostic sign of fracture of the base; and there can be no doubt that when such a discharge of cerebro-spinal fluid occurs either from the ear or nostrils, it *most probably* is connected with fracture. Operative interference is very seldom required in these fractures, our treatment being directed not against the broken bones, but against the accompanying cerebral lesions.

SKUNK (*Mephitis*), a genus of quadrupeds of the weasel family (*Mustelidæ*), but departing very considerably from the typical characters of that family, and approaching to the badgers and gluttons in general appearance, in habits, in the lengthened

Common Skunk (*Mephitis varians*).

claws of the fore-feet, in the plantigrade hind-feet, and in some of the teeth. There are six incisors and two canine teeth in each jaw, eight molars in the upper, and ten in the lower; the teeth generally resemble those of the polecat. Skunks depend very much for defence against enemies on an excessively fetid fluid, which is secreted by glands near the anus; and when assailed, they turn the rump towards

the assailant, elevate the tail, and discharge this fluid with considerable force. The odour proceeding from it, even when a dead S. had been flung into an enclosure, has been known to cause nausea to the inmates of an apartment with closed windows at the distance of 100 yards. So confident does the S. seem of the efficacy of its peculiar mode of defence, that it permits itself to be approached till it is just on the point of being seized, which, however, is only attempted by the inexperienced, when the battery is discharged. It is almost impossible to remove the odour from clothes. Dogs flee at once, and rub their noses on the ground till they bleed. Dogs that are aware of the S.'s powers, however, kill it by leaping upon it suddenly, and in such a way that they are not exposed to danger. There is much uncertainty concerning the species of S., as the colours vary considerably even in the same species; but there is no doubt of the existence of a number of species. They are found only in America, where they are very widely distributed from Hudson's Bay to the Strait of Magellan. The COMMON S. (*M. chinga* or *varians*) is about the size of a cat, generally black or blackish brown, with white streaks along the back. It inhabits burrows which it makes in the earth, feeds on mice, frogs, &c., and also on insects and fruits; and sometimes enters houses to plunder storerooms, where, if it is suddenly alarmed, everything is tainted with an intolerable odour. The fur of the skunk is known as Alaska Sable, and is very popular. See POLECAT.

SKYE (Icelandic, *Sky*, a cloud), the largest of the Scottish islands after Lewis, and the most northerly of the group known as the Inner Hebrides, forms part of the county of Inverness, from the mainland of which it is separated by a channel scarcely half a mile in breadth at its narrowest point, Kyle Rhea. Its extreme length, from south-east to north-west, is 47 miles; breadth, from 7 to 25 miles; but on account of the extraordinary number of inlets at all parts of the island, no point is above 4 miles from the sea. Area, 547 sq. m.; pop. (1861) 18,751. S. is for the most part mountainous and moory, but it contains some pleasant tracts of arable and pasture land, and one considerable plain, formerly the bed of a lake, in the parish of Kilmuir. The principal mountains are the Coolin Hills, which stretch irregularly chiefly from south-west to north-east, culminating in the sharp peak of Scoor-nan-Gillean (3220 feet) above Sligachan. The singularly jagged outline of these remarkable hills arrests the eye at a great distance, and forms the dominant feature in the view at almost every point round the island, and far out at sea. The most famous scene in this region is Loch Coiruisg, a small fresh-water lake near the head of the bay of Scavaig, all but encircled by frowning ridges of rock, shooting up at some points to the height of 3000 feet. It has been powerfully depicted by Sir W. Scott in *The Lord of the Isles*. Glen Sligachan, extending from the head of the loch of that name about 9 miles to Caumsunary, is by many considered the grandest glen in the Highlands. The scenery of Cuiraing, near the north of the island, has been truly styled 'unique.' The coast-scenery of S. is for the most part highly picturesque, and in many places very grand. Between Rhu-nam-Brarin and Loch Staffin, the coast-line presents magnificent basaltic formations, on a scale of magnitude considerably exceeding the Giants' Causeway or Staffa. Over these cliffs descend many remarkable waterfalls, and their bases are frequently worn into deep caves, some of which are of historical interest. One, near Portree, afforded a refuge to Prince Charles; another, on the west coast, was the temporary prison of Lady Grange. The largest arms of the sea are Loch Bracadale, Loch Dunvegan, and Loch Snizort; and the chief harbours are those of Portree, Uig, Grishernish, Lochbay, Dunvegan, Poltiel, and Harport.

The coasts abound in fish, the most important being herring, cod, ling, and saithe. Good oysters are found in several places. The herring-fishery is prosecuted in the season in all the bays; the cod and ling fishery is chiefly confined to Loch Dunvegan and Loch Snizort; and the salmon-fishery to Portree and the east coast. Lobster-fishing is also carried on to a considerable extent. There are no rivers of any magnitude; but salmon and sea-trout are got in some of the principal streams, at Skeabost, Portree, Ose, Hammer, &c. The fresh-water lakes are also small, and few in number. Deer are not numerous, nor are grouse. An excellent breed of hardy ponies used to be extensively reared, but the cultivation of sheep now engrosses almost exclusive attention from farmers. The climate of S. is exceedingly moist, the days throughout the year during which no rain falls being generally few in number. A register kept at Portree shews the rainfall in the years 1860—1865 to have been respectively 87·99, 139·04, 111·19, 148·89, and 89·54 inches. The climate is, however, mild and healthy, and the average standard of longevity uncommonly high. Agriculture in S. is comparatively unprofitable, owing to the moisture of the climate, and is, in fact, falling into entire neglect on some of the chief sheep-farms. The soil, however, is in many places excellent, and capable, in dry seasons, of yielding good cereal crops, while for turnips it is peculiarly suited.

The inhabitants are for the most part poor. In the districts where the men practise fishing, nearly the whole of the adult males go to the Caithness fisheries in summer, while from all parts of the island, young men and women go in troops to the south in search of field-labour. Potatoes and fish are the general diet, meat being a rare luxury. The population is chiefly Celtic, with, however, a considerable mixture of the Norse element. Gaelic is still universally spoken, but is gradually giving place to English. The chief proprietors are still, as of old, Lord Macdonald, whose seat, Armadale Castle in Sleat, is one of the most beautiful in all its surroundings to be seen on the Scottish coasts, and Macleod of Macleod, whose ancient castle of Dunvegan, picturesquely seated on a rock, has been pleasantly commemorated by Dr Johnson and Sir Walter Scott. Around these residences are the principal plantations to be seen in Skye. The principal port of S. is Portree, a picturesquely situated village of about 600 inhabitants, to which steamers regularly ply from Glasgow. Other villages, also calling-points of the steamers, are Kyleakin (Hakon's Strait), Broadford, and Dunvegan. The principal exports are cattle and sheep, wool, fish, shell-fish, and eggs. At Portree, there is a flourishing tweed manufactory, the only one in the island. The celebrated distillery of Carabost (or Talisker) is now given up. The inhabitants are, with the exception of a few families, all Presbyterians, and, as in the rest of the Highlands, chiefly adherents of the Free Church. Of the smaller islands near S., the chief are Raasay (q. v.), Ronay, Scalpay, Pabbay, Soay, all of which are inhabited.

SKY'RO (anc. *Scyros*), an island of the Grecian Archipelago, the largest member of the northern Sporades, 25 miles north-east of Cape Koumi, Eubœa. Its length is 19 miles; area estimated at about 60 sq. miles. S. is very mountainous and uncultivated in the south; but the northern part, though also hilly, has several fertile plains, which

produce as fine wheat as any grown in the archipelago. The only town in the island is Skyro, or St George, which is built on a high peak on the eastern coast, the broad summit of which is occupied by the ruins of a castle, and was the site of 'the lofty Scyros' of Homer. There are several relics of antiquity in the island. Pop. 2620.

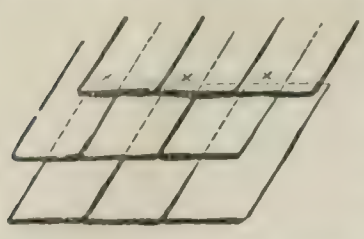
SLAGS, called otherwise Scoriæ or Cinders, are fused compounds of silica in combination with lime, alumina, or other bases; and result as secondary products from the reduction of metallic ores. More or less of the metal always remains in a slag; in the early days of iron-smelting, the proportion of metal thus wasted was so great, that some old slags have been profitably smelted in recent times. Slags being silicates, are of the nature of glass, and externally have a glassy, crystallised, or stone-like character. Beautifully crystallised specimens are occasionally to be met with at smelting-works. They vary very much in colour, and are sometimes so prettily veined and marbled, that attempts have been made to apply them to ornamental purposes. Millions of tons of slag are annually produced at the iron-smelting works of Great Britain, but almost the only use to which it has yet been successfully applied is in the making of square blocks or bricks for building purposes. The slag is run into moulds, either as it issues from the blast-furnace, or after being remelted; and it is found to be a very durable material. Broken slag is also used as a covering for roads, but its brittleness and sharpness are objectionable qualities for this purpose. Several patents, beginning so far back as 1728, have been taken out for casting slag into articles of a more ornamental kind, but hitherto they have not been commercially successful.

In an archæological point of view, slags are interesting as pointing out the sites of ancient smelting-works, and as affording a clue to the primitive methods of obtaining the metals from their ores.

SLANDER is an injury to a person's character and reputation caused by spoken words. It is difficult to define what kind of injuries of this nature are actionable, but in general whatever imputes disgraceful, fraudulent, or dishonest conduct, or even tends to make a man contemptible in his private relations, and shunned by his friends and neighbours, is a slander. Thus, whatever imputes a crime or indictable offence, or a contagious disease, is a slander. There are some epithets, however, which are not actionable unless some special damage is directly caused thereby, as calling a man a scoundrel, swindler, rogue, gambler, liar, &c. To call a woman a whore is also not actionable, unless she can shew that she has lost offers of marriage, &c. thereby. Words imputing gross ignorance or misconduct affecting one's trade or profession, are, however, actionable, as calling a man a bankrupt grocer, a quack doctor, &c. See also LIBEL. The remedy for slander is an action at law for damages. Though certain words when spoken will not amount to slander, yet, if printed or written, they will sometimes become so, as calling one a rogue, swindler, rascal, &c.

SLANG, a word originally borrowed from the gipsy tongue, where it is used for the secret language of that tribe. In its usual signification, it denotes a burlesque style of conversational language, originally found only among the vulgar, but now more or less in use in both Great Britain and America among persons in a variety of walks in life. It is somewhat allied to, though not identical with, *cant* (in French *argot*), the language used for purposes of concealment by thieves and vagrants of all descriptions.

Slang is not exclusively of modern date. It was known in the classic ages of Greece and Rome, and abounds in the writings of Aristophanes, Plautus, Terence, and Martial. Every modern European language has its slang. In England, the 'Rump,' the 'Barebones Parliament,' the terms 'Roundheads,' 'Puritans,' 'Quakers,' all belonged to the slang of the 17th century. *Hudibras* and the dramatic works of last century abound in slang. Old English slang was coarser than that now in use, but the greater portion of its phraseology had a somewhat restricted circulation, not permeating every species of conversation to the extent that modern slang does. Towards the close of last century, the slang vocabulary received large additions from pugilism, racing, and 'fast life;' and its fashionable vulgarisms came into great favour during the minority of the Prince Regent. In the present century, the growth of refinement in manners and ideas has not banished slang, but given it a more familiar and utilitarian character, while it has been introduced in some measure into circles where it was formerly unknown.



Slang consists in part of new words, and in part of words of the legitimate language invested with new meanings, such as are assigned to the verbs to *cut*, to *do*. Many slang expressions are derived from thieves' cant, and some from the gipsy tongue. Their derivations are often indirect, arising out of fanciful allusions and metaphors, which soon pass out of the public mind, the word remaining, while its origin is forgotten. The origin of much of the current slang may be traced to the universities of Oxford and Cambridge, and the great public schools of England. There is not an institution connected with the university which has not its slang equivalent (e. g., 'plucked,' 'little go').

There is a slang attached to various professions, occupations, and classes of society. The slang of English fashionable life and fashionable novels comprises a number of French words and phrases, whose application is often very different from what is current in France. The *beau monde*, a *chaperon*, a marriage being on the *tapis*, are expressions which, in their English sense, are utterly unknown in Paris. To the slang of military life, Hindustani has contributed its quota of words, imported by officers who have resided long in India. We have also parliamentary slang, religious slang, literary slang, civic slang, and shopkeepers' slang.—Many curious details regarding slang in all its departments are to be found in Hotten's *Slang Dictionary* (Lond. 1865).

SLATE, or CLAY-SLATE (Fr. *esclat*, a shiver or splinter), is a highly metamorphosed argillaceous rock, fine-grained and fissile, and of a dull blue, gray, green, or black colour. It splits into thin laminæ or plates, that are altogether independent of the layers of deposit; though sometimes coinciding with them, they more frequently cross them at different angles. See CLEAVAGE. Some rocks that split into the thin plates of the original stratification, are popularly but erroneously named slate, as the thin bedded sandstones properly called flagstones or tilestones, the fissile shales of Cambrian and Silurian age, and the metamorphic, gneiss, and mica schist, whose planes of division correspond to their stratification. True slate is a very compact rock, little liable to be acted upon by atmospheric agencies. It is chiefly obtained from Palæozoic strata, but it is found also among more recent rocks. It is used for various purposes, being split into thin slabs of small size for the roofing of houses, and into larger slabs for fitting up dairies, &c., and even for making billiard-tables, and split and polished by means of pumice for writing-slates. There are extensive quarries of

roofing-slate in Wales and in the Western Highlands of Scotland, and in the Ardennes in France, some of which have been wrought for a long time, and give employment to a great number of workmen. A hard compact slate is best for roofing; that which is porous imbibes water, the freezing of which splits it in winter, whilst it affords also a soil for mosses, which soon injure the roof.

In roofing with slates, it is necessary to put on the slates in two thicknesses, so that the sloping joints may be covered by the overlap of the course above. Besides this, the third course must also cover the first by an inch or two, to prevent rain from penetrating. Slates are generally laid upon boarding, and bedded in lime, and nailed with malleable-iron nails, japanned, so as to prevent them from rusting. When large strong slates are used, they may be nailed to strong laths in place of boarding. Welsh slates are the cheapest and most generally used; but Easdale or Ballachulish slates, from the west of Scotland, are stronger and better when the roofs are liable to be injured.

SLATE-PENCILS are either cut or turned sticks of slate, or they are made by pressing moistened slate-powder until it is firm enough to be made into pencils.

SLAVE-COAST, a division of the coast of Upper Guinea, Africa, lying between the rivers Volta and Lagos. See GUINEA.

SLAVERY. A slave is an individual who is the property, or at the disposal of another, who has a right to employ or treat him as he pleases. Such is the state of the slave in the most absolute sense of the term; but slavery has been subjected to innumerable limitations and modifications.

Slavery probably arose at an early period of the world's history out of the accident of capture in war. Savages, in place of massacring their captives, found it more profitable to keep them in servitude. All the ancient oriental nations of whom we have any records, including the Jews, had their slaves. The Hebrews were authorised by their law to possess slaves, not only of other races, but of their own nation. The latter were generally insolvent debtors, who had sold themselves through poverty, or thieves who lacked the means of making restitution; and the law dealt with them far more leniently than with stranger slaves. They might be redeemed; and if not redeemed, became free in the space of seven years from the beginning of their servitude; besides which, there was, every fiftieth year, a general emancipation of native slaves.

Slavery existed in ancient Greece: in the Homeric poems, it is the ordinary destiny of prisoners of war; and the practice of kidnapping slaves is also recognised. Ulysses himself narrowly escaping a fate of this kind. None of the Greek philosophers considered the condition of slavery objectionable on the score of morals. Aristotle defends its justice on the ground of a diversity of race, dividing mankind into the free and the slaves by nature; while Plato only desires that no Greeks should be made slaves. One class of Greek slaves were the descendants of an earlier and conquered race of inhabitants, who cultivated the land which their masters had appropriated, paid rent for it, and attended their masters in war. Such were the Helots in Sparta, the Penestæ in Thessaly, the Bithynians at Byzantium, &c., who were more favourably dealt with than other slaves, their condition somewhat resembling that of the serfs of the middle ages. They could not be sold out of the country, or separated from their families, and were even capable of acquiring property. Domestic slaves obtained by purchase were the unrestricted property of their owners, who could dispose of them at pleasure. In Athens, Corinth, and the other commercial states, they were very numerous, and mostly barbarians. They were employed partly in domestic service, but more as bakers, cooks, tailors, or in other trades, and in mines and manufactories; and their labour was the means by which the owner obtained profit for his outlay in their purchase. These slaves were, for the most part, purchased; but few were born in their master's family, partly from the general discouragement of the cohabitation of slaves, and partly from the small number of the female in comparison with the male slaves. An extensive traffic in slaves was carried on by the Greek colonists in Asia Minor with the interior of Asia; and another source of supply arose from the practice common among Thracian parents of selling their children. In Greece in general, and especially at Athens, slaves were mildly treated, and enjoyed a large share of legal protection. According to Demosthenes, a slave at Athens was better off than a free citizen in many other countries.

The Roman condition of slavery differed in some particulars from that of Greece. All men were considered by the Roman jurists to be free by natural law; while slavery was regarded as a state contrary to natural law, but agreeable to the law of nations, when a captive was preserved, instead of being slain (hence the name *servus*, quasi *servatus*); or agreeable to the civil law, when a free man sold himself. In earlier times, there was no restriction on the master's power of punishing or putting to death his slave; and even at a later period, when the law on this head was much modified, slaves were used with considerable rigour. The estimation in which their lives were held is illustrated by the practice of gladiatorial combats, as also by the conduct of Vedius Pollio, who, in the polite age of Augustus, flung such slaves as displeased him into his fishponds, to feed his lampreys, and on the matter being brought under the emperor's notice, was visited with no severer punishment than the destruction of his ponds. Old and useless slaves were often exposed to starve in an island of the Tiber. Under the Empire, the cruelty of masters was in some degree restrained by law. It was enacted, that a man who put to death his own slave without cause should be dealt with as if the slave had been the property of another; and that if the cruelty of the master was intolerable, he might be compelled to sell the slave. A constitution of Claudius declared the killing of a slave to be murder, and it was also enacted, that in sales of slaves, parents and children, brothers and sisters, should not be separated. A slave could not contract marriage, and no legal relation between him and his children was recognised. The children of a female slave followed the status of their mother. There were various ways in which a slave might be manumitted, but the power of manumission was restricted by law. The harbouring of a runaway slave was illegal. The number of slaves in Rome, originally small, was increased much by war and commerce; and the cultivation of the soil came, in the course of time, to be entirely given up to them. During the later republic and empire, persons in good circumstances kept an immense number of slaves as personal attendants; and the possession of a numerous retinue of domestic slaves was matter of ostentation—200 being no uncommon number for

one person. A multitude of slaves were also occupied in the mechanical arts and the games of the amphitheatre. Originally, a slave was incapable of acquiring property, all his acquisitions belonging to his master; but when slaves came to be employed in trade, this condition was mitigated, and it became the practice to allow a slave to consider part of his gains, called his *peculium*, as his own, a stipulation being sometimes made that he should purchase his freedom with his peculium, when it amounted to a specific sum.

Though the introduction of Christianity did not do away with slavery, it tended to ameliorate the condition of the slave. Justinian did much to promote the eventual extinction of slavery; and the church excommunicated slave-owners who put their slaves to death without warrant from the judge. But the number of slaves again increased; multitudes being brought with them by the barbarian invaders, who were mostly Slavonian captives (whence our word *slave*); and in the countries which had been provinces of the empire, slavery continued long after the empire had fallen to pieces, and eventually merged into the mitigated condition known as serfdom, which prevailed all over Europe in the middle ages, and has been gradually abolished in modern times. See SERF. But though the practice of selling captives taken in war as slaves ceased in the Christian countries of Europe, a large traffic in slaves continued among Mohammedan nations, by whom Christian captives were sold in Asia and Africa; and in the early middle ages, the Venetian merchants traded largely in slaves, whom they purchased on the coast of Slavonia, to supply the slave-markets of the Saracens.

The negro slavery of modern times was a sequel to the discovery of America. Prior, however, to that event, the negroes, like other savage races, enslaved those captives in war whom they did not put to death, and a considerable trade in slaves from the coast of Guinea was carried on by the Arabs. The deportation of the Africans to the plantations and mines of the New World doubtless raised the value of the captive negro, and made slavery rather than death his common fate; while it may also have tempted the petty princes to make war on each other, for the purpose of acquiring captives, and selling them. The aborigines of America having proved too weak for the work required of them, the Portuguese, who possessed a large part of the African coast, began the importation of negroes, in which they were followed by the other colonisers of the New World. The first part of the New World in which negroes were extensively used was Hayti, in St Domingo. The aboriginal population had at first been employed in the mines; but this sort of labour was found so fatal to their constitutions that Las Casas, bishop of Chiapa, the celebrated protector of the Indians, interceded with Charles for the substitution of African slaves as a stronger race; the emperor accordingly, in 1517, authorised a large importation of negroes from the establishments of the Portuguese on the coast of Guinea. Sir John Hawkins was the first Englishman who engaged in the traffic, in which his countrymen soon largely participated, England having exported no fewer than 300,000 slaves from Africa between the years 1680 and 1700; and between 1700 and 1786, imported 610,000 into Jamaica alone. The slave-trade was attended with extreme inhumanity; the ships which transported the negroes from Africa to America were overcrowded to such an extent that a large proportion died in the passage; and the treatment of the slave after his arrival in the New World depended much on the character of his master. Legal restraints were, however, imposed in the various European settlements, to protect the slaves from injury; in the British colonies, courts were instituted to hear their complaints; their condition was to a certain extent ameliorated, and the flogging of women was prohibited. But while slavery was thus legalised in the British colonies, it was at the same time the law of England (as decided in 1772 in the case of the negro Somerset), that as soon as a slave set his foot on English soil he became free; though, if he returned to his master's country, he could be reclaimed.

Before the idea of emancipation was contemplated, the efforts of the more humane portion of the public were directed towards the abolition of the traffic in slaves. In 1787, a society for the suppression of the slave-trade was formed in London, numbering Messrs W. Dillwyn, Thomas Clarkson, and Granville Sharp among its original members. The most active parliamentary leader in the cause was Mr William Wilberforce, whose views were seconded by Mr Pitt. In February 1788, an order of the crown directed that an inquiry should be made by a committee of the Privy Council into the state of the slave-trade; and an act was passed to regulate the burden of slave-ships, and otherwise diminish the horrors of the middle-passage. A bill introduced by Mr Wilberforce for putting an end to the further importation of slaves was lost in 1791. Meanwhile, our conquest of the Dutch colonies having led to a great increase in the British slave-trade, an order in council, in 1805, prohibited that traffic in the conquered colonies; and in the following year, an act was passed forbidding British subjects to take part in it, either for the supply of the conquered colonies or of foreign possessions. In the same year, a resolution moved by Mr Fox for a total abolition next session, was carried in the Commons, and on Lord Granville's motion, adopted in the Lords; and the following year, the general abolition bill, making all slave-trade illegal after 1st January 1808, was introduced by Lord Howick (afterwards Earl Grey) in the House of Commons, was carried in both Houses, and received the royal assent on 25th March 1807. British subjects, however, continued to carry on the trade under cover of the Spanish and Portuguese flags; the slave-ships were more crowded than ever, from the necessity of avoiding capture, and the negroes were not unfrequently thrown overboard on a pursuit. The pecuniary penalties of the act were discovered to be inadequate to put down a traffic so lucrative as to cover all losses by capture. Mr Brougham therefore, in 1811, introduced a bill, which was carried unanimously, making the slave-trade felony, punishable with 14 years' transportation, or from three to five years' imprisonment with hard labour. An act of 1824 declared it piracy, and as such, a capital crime, if committed within the Admiralty jurisdiction; and the statute of 1837, mitigating the criminal code, left it punishable with transportation for life. Among the philanthropic projects due to the exertions of the Anti-slavery Society was the establishment of the colony of Sierra Leone, on the coast of Africa, which had been formed by the British government in 1787, in order to shew the possibility of obtaining colonial produce without slave-labour, and after the abolition of the slave-trade, became a settlement for the negroes captured by British cruisers.

The United States of America abolished the slave-trade immediately after Great Britain, and the same was in the course of time done by the South American republics of Venezuela, Chili, and Buenos Ayres, by Sweden, Denmark, Holland, and during the Hundred Days after Napoleon's return from Elba, by France. Great Britain, at the peace, exerted her influence to induce other foreign powers to adopt a

similar policy; and eventually nearly all the states of Europe have passed laws or entered into treaties prohibiting the traffic. The accession of Portugal and Spain to the principle of abolition was obtained by treaties of date 1815 and 1817; and by a convention concluded with Brazil in 1826, it was declared piratical for the subjects of that country to be engaged in the slave-trade after 1830. By the conventions with France of 1831 and 1833, to which nearly all the maritime powers of Europe have since acceded, a mutual right of search was stipulated within certain seas, for the purpose of suppressing this traffic. The provisions of these treaties were further extended in 1841 by the Quintuple Treaty between the five great European powers, subsequently ratified by all of them except France. The Ashburton treaty of 1842 with the United States provided for the maintenance by each country of a squadron on the African coast; and in 1845, a joint co-operation of the naval forces of England and France was substituted for the mutual right of search.

All these efforts have not succeeded in altogether abolishing the slave-trade; and the encouragement which its continuance has given to the petty chieftains to enrich themselves at the expense of their fellow-countrymen, has tended to retard the progress of civilisation in Africa. The flag of Portugal, and occasionally of Spain, is believed to have been used with connivance of the authorities for carrying on the traffic, and no small difficulty has been found in obtaining the sincere co-operation of either of these two countries. In 1857, a scheme was sanctioned by the French government for conveying *free* negroes to the colonies of Guadaloupe and Martinico; but it gave rise to abuses, and the seizure of two vessels engaged in this enterprise as slavers by the Portuguese, with the disclosures which followed, led to its being given up.

The limitation of the supply of negroes naturally led, among other good results, to a greater attention on the part of the masters to the condition of their slaves. But the attention of British philanthropists was next directed towards doing away with slavery altogether in our colonies. Societies were formed with this end, an agitation was set on foot, and attempts were made, for some time without success, to press the subject of emancipation on the House of Commons. At length, in 1833, a ministerial proposition for emancipation was introduced by Mr. Stanley, then Colonial Secretary, and an emancipation bill passed both Houses, and obtained the royal assent, 28th August 1833. This act, while it gave freedom to the slaves throughout all the British colonies, at the same time awarded an indemnification to the slave-owners of £20,000,000. Slavery was to cease on 1st August 1834; but the slaves were for a certain duration of time to be apprenticed labourers to their former owners. Objections being raised to the apprenticeship, its duration was shortened, and the complete enfranchisement took place in 1838. While this measure reflects the highest credit on the humanity which prompted it, it is not to be denied that emancipation has failed to benefit the slave or raise his condition to the extent hoped for by its more enthusiastic supporters.

The French emancipated their negroes in 1848; as did most of the new republics of South America at the time of the revolution; while the Dutch slaves had freedom conferred on them in 1863. In Hayti, slavery ceased as far back as 1791, its abolition having been one of the results of the negro insurrection of that year. Slavery still exists in the Spanish and Portuguese colonies.

Of slavery in the United States it is recorded hat the first slaves introduced into the territory of the original colonies were sold from a Dutch vessel which landed twenty at Jamestown, Va., in 1620. Says the historian Bancroft, "It is not easy to conjecture how many negroes were imported into the English continental colonies * * * *. Previous to the year 1740 there may have been introduced into our country nearly one hundred and thirty thousand; before 1776, a few more than three hundred thousand."

The importation of slaves was received with great disfavor by the colonists. Laws were passed by the colony of Virginia restraining the practice; but their wishes were disregarded by the king, who, on the 10th day of December, 1770, issued an instruction, under his own hand, commanding the governor, "under pain of the highest displeasure, to assent to no law by which the importation of slaves should be in any respect prohibited or obstructed." In April, 1772, this rigorous order was solemnly debated in the Assembly of Virginia. A memorial to the king himself was prepared, declaring the importation of slaves from the coast of Africa "a trade of great inhumanity and dangerous to the very existence of his majesty's American dominions," and praying that the interest of the few of his subjects in Great Britain who might "reap emolument from this sort of traffic" might be disregarded when placed in competition with the interests of the entire colonies. Their petition was of no avail; and with the further development of the country the institution of slavery, regarded at first as a moral and political evil, came to be recognized in the Southern States as a social necessity. In 1790 the slaves in the United States numbered 697,897; in 1810, 1,191,364; in 1820, 1,538,038; in 1830, 2,009,043; in 1840, 2,487,455; in 1850, 3,204,313; and in 1860, 3,952,801.

In 1780 Pennsylvania provided for the gradual emancipation of her slaves. Massachusetts abolished slavery by the adoption of her constitution in 1780. Rhode Island and Connecticut gradually emancipated their slaves. In 1799 New York passed a gradual emancipation act, and in 1817 another act, declaring all slaves free on the 4th of July, 1827. New Jersey passed a gradual emancipation act in 1804, and in 1863 slavery was abolished in the states of the Union then in rebellion, and by Art. XIII. of the Constitution in 1865.

SLAVES, or SLAVONIANS (native name *Slowene* or *Slowane*, derived by some from *Slawa*, fame, but better from *Slowo*, a word; thus meaning 'speaking' or 'articulate,' as distinguished from other nations, whom they called Niemetz, or 'Mutes'), the general name of a group of nations belonging to the Aryan family, whose settlements extend from the Elbe to Kamtchatka, and from the Frozen Sea to Ragusa on the Adriatic, the whole of Eastern Europe being almost exclusively occupied by them. They were settled in these regions before the dawn of history, and are comprehended by ancient writers under the designations of Sarmatians and Scythians. The original names of the Slavic tribes seem to have been Winds or Wends (*Venedi*) and Serbs. The former of these names occurs among the Roman writers, and later, in Jornandes, in connection with the commercial peoples of the Baltic Sea; the latter is spoken of by Procopius as the ancient name common to the whole Slavic stock. The earliest historical notices extant represent the S. as having their chief settlements about the Carpathians, from which they spread northward to the Baltic, westward as far as the Elbe and the Saal, and later, after the overthrow of the kingdom of the Huns

southward beyond the Danube, and over the whole peninsula between the Adriatic and the Black Sea. These migrations ceased in the 7th c.; the division of the Slavic stock into separate branches became now more complete, and gradually they began to form into independent states. The various sections of the stock may be divided into two groups, the south-eastern and the western; the first comprehends—(1), Russians; (2), Bulgarians; (3), Illyrians (Serbs, Croats, Wends): the second—(1), Lechs (Poles, Silesians, Pomeranians); (2), Czechs or Bohemians (Czechs, Moravians, Slovaks); (3), Polabians, comprising the Slavic tribes of N. Germany, who are fast disappearing, by being absorbed in the Teutonic population. With the exception of Russia (to which may be added Servia and Montenegro, as maintaining a kind of independence), the once numerous Slavic kingdoms (Bohemia, Bulgaria, Moravia, Poland, &c.) have lost their sovereignty, and been incorporated in other states, chiefly Turkey, Austria, Prussia, and Saxony. The Polabians never attained any distinct political footing. The whole of the Slavic populations are estimated at upwards of 80 millions.

The S. are represented by ancient writers as an industrious race, living by agriculture and the rearing of flocks and herds; as hospitable and peaceful, and making war only in defence. The feeling of nationality was strong among them. The government had a patriarchal basis, and chiefs or princes were chosen by assemblies. But contact with the feudal institutions of the Roman-German empire gradually altered this primitive constitution; the Slavic princes strove after unlimited power, like that of the emperors; and the chiefs sought to dominate over the people, like the feudal nobility. In the course of the 11th, 12th, and 13th centuries, nobility became a hereditary privilege throughout the Slavic states. The worst kind of feudalism fairly took root, and the people sank into the condition of serfs. Between them and the nobles there was no third or middle class, as the peculiar privileges of the nobility prevented the growth of cities. See SERF, RUSSIA.

The *religion* of the ancient S., like that of the Teutonic nations, seems to have been, in many of its features at least, a kind of nature-worship; not, however, without the idea of a One supreme power, to whom the other agencies were subordinate. From this, some authorities infer that the system was originally a monotheism, which in process of time had become obscured and confused by the infusion of foreign elements, and thus degenerated into polytheism, and finally pantheism. The chief deity, whose worship seems to have been common to all the Slavic tribes, was Swiatowit, with whom were associated, on a nearer footing of equality than the other gods, Perun and Radegast—if, indeed, these three names do not merely denote different personations or manifestations of the same power. In this trinity, Swiatowit is considered as most analogous to Mars and Zeus, Perun to Jupiter and Thor, and Radegast to Mercury and Odin. Of the numerous gods of an inferior order, we may name Prowe, god of justice; Prija (=Freya), Venus; Bjelbog, the White god, and Cernobog, the Black god; together with multitudes of demons and spirits good and bad. The images of the Slavic divinities (a stone statue of Swiatowit was in recent times discovered in Eastern Galicia) had a striking resemblance to those of India. Swiatowit had four heads, Rugewit (the god of war) had seven faces, and Perun four, and so on. The S. seem to have been not without some crude notion of existence and retribution after death. Worship was performed in groves and temples, cattle and fruits being offered by the priests, whose office must have been originally performed by the head of the family or chieftain, as the common name for priest and prince (*knicz*) shews. —The eastern S. received Christianity from Byzantium in the 9th c., through the instrumentality of Cyril (q. v.) and Methodius; the western, from Rome and Germany.—See Schafarik, *Slaw. Alterthümer* (Ger. translation, Leip 1843).

SLA'VIC LANGUAGE AND LITERATURE. The term Slavic, as applied to language or race, is a generic name (like Celtic or Teutonic) for a group of kindred languages and peoples belonging to the great Indo-Germanic or Aryan family. In its roots and structure, the Slavic language exhibits a remarkable similarity to Sanscrit, but has become European, so to speak, in the course of a long literary development, begun *before* that of any of the other European families. Its peculiarities are quite marked. The leading characteristics of the Slavic tongues are the completeness of their system of declensions, the want of articles, the absence of pronouns in the conjugation of the verb, pure vowel-endings, the fixed quantity of the syllables, the free construction of sentences, and the richness of their vocabulary. The earliest dialect of Slavic that received a literary culture was the 'Old Bulgarian,' better known as the 'Church Slavic,' which, however, failed to become the literary vehicle for all the Slavic peoples, inasmuch as the special dialect of each gradually acquired a literature of its own. Altogether, writers reckon eight distinct extant dialects of Slavic: 1. The 'New Bulgarian;' 2. The Russian; 3. The Servian or Illyrian; 4. The Polish; 5. The Bohemian; 6. The Slovak; 7. The Wendic; 8. The Polabic. Such of these as merit special treatment have received it. —See BOHEMIAN LANGUAGE AND LITERATURE, POLISH LANGUAGE AND LITERATURE, RUSSIAN LANGUAGE AND LITERATURE, SERVIAN LANGUAGE AND LITERATURE.—In regard to Slavic literature, considering the articles just mentioned, it is only necessary to state that at present the Russian branch of the Slavic is the richest in the number of its published works; but as regards literary merit, the Polish ranks first, having cultivated with great success almost all sorts of literature, and possessing in particular a very exquisite poetry. The Bohemian and Servian literatures both contain many fine and distinctively original productions, worthy of being more widely known than they are.—See Schafarik's *History of the Slavic Language and Literature* (Ofen, 1816); and Mickiewicz's *Lectures on the Slavic Literature* (4 vols. Leip. 1849).

SLAVO'NIA, a province of Austro-Hungary, east of Croatia (q. v.), with which it is now politically united. It is bounded on the N. by the Drave, on the E. by the Danube, on the S. by the long strip of marsh-land known as the Slavonian Military Frontier, which stretches between it and the Save. Area of the crown-lands of Croatia (q. v.) and Slavonia, 7074 sq. m.; pop. 1,023,858. The greater part of the surface consists partly of eminences clothed with vines and fruit-trees, and partly of fertile and swampy plains. The mountains are rich in coal, marble, and mineral springs. The principal products are all sorts of grain, particularly maize and wheat, leguminous plants, and fruit in abundance, apples, pears, plums, walnuts, chestnuts, melons, wine, &c. There is little manufacturing industry in Slavonia.—The inhabitants of S. belong to the Slavic family (see SLAVES), and call their land Slavonska; themselves Slavonaz. They speak the so-called Illyrian or Servian tongue. See SERVIAN LANGUAGE AND LITERATURE. The Slavonians proper are a handsome, tall, and

slender race. The prevailing form of religion is the Roman Catholic, but the non-united Greek Church also numbers many adherents. Education is still in a backward state. Capital of the country, Eszék (q. v.).

SLEEP. This term is employed to designate that state of suspension of the sensory and motor functions which appears to alternate in all animals with the active condition of those functions, and which may be made to give place to it by the agency of appropriate impressions upon the sensory nerves. This definition, which we have borrowed from Dr Carpenter's article on 'Sleep' in Todd's *Cyclopædia of Anatomy and Physiology*, may seem somewhat complex, but cannot be simplified without rendering it less stringent. The necessity for sleep arises from the fact, that the exercise of the animal functions is in itself destructive of the tissues of the organs which minister to them, so that if the waste produced by their action were not duly repaired, they would speedily become unfit for further use; and it is on the nutritive regeneration of the tissues which takes place during true healthy sleep that its refreshing power depends. While the sensory and motor functions are suspended during the condition we designate as sleep, the organic functions are uninterruptedly carried on, the respiratory, cardiac, and peristaltic movements proceeding with equal uniformity during the sleeping and waking states.

There can be no doubt that the state of sleep is one to which there is a periodical tendency, and that this disposition is so arranged as to correspond in its recurrence with the diurnal revolution of the earth. Although in man and most animals night is, from its darkness and silence, the natural period for repose, yet there are numerous exceptions to the rule. For example, amongst lepidopterous insects, butterflies are active during the day, hawk-moths during the twilight, and moths during the night. Amongst birds, the goatsucker, or night-jar, and the owls, are nocturnal, and, as a general rule, the same is the case with carnivorous animals. The causes of sleep may be divided into the direct and the predisposing. The direct cause of sleep is that feeling of exhaustion or fatigue which is usually experienced when the waking activity has continued during a considerable portion of the twenty-four hours—a feeling that the brain requires repose; and, in fact, unless the brain be in an abnormal condition, sleep will at last supervene, from the absolute inability of that organ to sustain any further demands upon its energy. Among the predisposing causes which favour the access of sleep, we must especially notice 'the *absence* of sensorial impressions; thus, darkness and silence usually promote repose; and the cessation of the sense of muscular effort which usually takes place when we assume a position that is sustained without it, is no less conducive to slumber.'—Carpenter's *Human Physiology*, 6th ed. 1864, p. 592. On the other hand, persons accustomed to live where there is a continuous noise, as in the neighbourhood of mills or forges, often cannot sleep if the noise is suspended. These cases, however, probably fall within the next general predisposing cause—namely, the *monotonous repetition* of sensorial impressions. Thus, the droning voice of an unimpressive reader or preacher, the gentle ripple of the ocean, the hum of bees, the rustling of foliage, and similar monotonous impressions on the auditory nerves, are usually provocative of sleep. In these and similar cases, the influence of the impressions is exerted in withdrawing the mind from the consciousness of its own operations, and in suspending the directing power of the will; and this is the case, says Dr Carpenter, 'even when the attention is, in the first instance, *voluntarily* directed to them, as in some of the plans which have been recommended for the induction of sleep, when there exists no spontaneous disposition to it. In other methods, the attention is fixed upon some internal train of thought, which, when once set going, may be carried on automatically, such as counting numbers, or repeating a Greek verb. In either case, when the sensorial consciousness has been once steadily fixed, the monotony of the impression (whether received from the organ of sense or from the cerebrum) tends to retain it there; so that the will abandons, as it were, all control over the operations of the mind, and allows it to yield itself up to the soporific influence. This last method is peculiarly effectual when the restlessness is dependent upon some mental agitation, provided that the will has power to withdraw the thoughts from the exciting subject, and to reduce them to the tranquillising state of a mere mechanical repetition.'

The access of sleep is sometimes quite sudden, the individual passing at once from a state of complete mental activity to one of entire torpor. More generally, however, it is gradual, the mind while remaining poised, as it were, between sleep and the opposite condition being 'pervaded by a strange confusion which almost amounts to wild delirium; the ideas dissolve their connection with it one by one; and its own essence becomes so vague and diluted that it melts away in the nothingness of slumber.'—Macnish, *Philosophy of Sleep*, p. 21. The amount of sleep required by man is affected by so many conditions (amongst which must be especially mentioned *age*, *temperament*, *habits*, and previous exhaustion), that no general rule can be laid down on the subject. The condition of the *fœtus* may be regarded as one of continuous slumber: on its first entrance into the world, the infant passes most of its time in sleep, and this is particularly the case in children prematurely born, such children seeming only to awake for the purpose of receiving food. During the whole period of growth, in which it is necessary that the *constructive* operations of the body should preponderate over the *destructive* processes, an excess of sleep is required; and by the time that adult age has been attained, and the constructive and destructive processes balance each other, the necessary amount of sleep has gradually fallen to about one-third or less of the diurnal cycle. In very old age, again, in consequence of the deficient energy of the nutritive process, a larger amount of sleep is required. With regard to the influence of temperature, it is observed that a plethoric habit of body usually predisposes to sleep, while thin wiry people of a nervous temperament require comparatively little sleep. Persons of lymphatic temperament are usually great sleepers, but this is probably due, as Dr Carpenter suggests, to the fact, that 'through the dulness of their perceptions they are less easily kept awake by sensorial or mental excitement' than persons of a happier temperament. The influence of habit is by no means inconsiderable on the amount of sleep required by individuals, and this influence may be brought to act on the protraction as well as the abbreviation of the usual period: as extreme examples, we may mention that General Eliott, celebrated for his defence of Gibraltar, did not sleep more than four hours out of the twenty-four (which is probably the smallest allowance for rest compatible with a life of vigorous exertion); while Dr Reid, the metaphysician, could take as much food, and afterwards as much sleep, as were sufficient for two days. Moreover, the influence of habit in producing an aptitude for repose, or a readiness to wake at particular periods, is well known.

The sleep of soldiers during a siege, of sailors or others who must take their rest as they best can, will often come on at command; nothing more being necessary to induce it than to assume a recumbent, or, at all events, an easy position, and to close the eyes. Thus, Captain Barclay, in his celebrated match, in which he walked 1000 miles in 1000 successive hours, very soon got into the habit of falling asleep the moment he lay down.

The condition of the great nervous centres during sleep is a subject of much interest, on which considerable light has recently been thrown by the observations of Mr Durham.* These observations were made on a dog from which a portion of bone about as large as a shilling was removed from the parietal region of the skull, and the subjacent dura mater cut away so as to expose the brain; and Mr Durham draws the following conclusions from them: 1. Pressure of distended veins upon the brain is not, as is generally believed, the cause of sleep, for during sleep the veins are *not* distended. 2. During sleep, the brain is in a comparatively bloodless condition; and the blood in the encephalic vessels is not only diminished in quantity, but moves with diminished rapidity; and this is corroborated by the observations of Dr J. Hughlings Jackson on the ophthalmoscopic condition of the retina during sleep, the optic disc being then whiter, the arteries smaller, and the retina generally more anæmic than in the waking state. 3. The condition of the cerebral circulation during sleep is, from physical causes, that which is most favourable to the nutrition of the brain-tissue.

This article would be imperfect without a brief reference to the conditions in which there is either an excess or a deficiency of sleep. There are numerous instances on record in which sleep has been continuously prolonged for weeks, or even months. Dr Carpenter refers to two such cases, namely, those of Samuel Chilton (*Phil. Trans.* 1694) and Mary Lyall (*Trans. Roy. Soc. Edin.* 1818). Blanchet, a French physician, has recently recorded three cases of what he terms 'constitutional lethargic slumber' in the *Comptes Rendus*, 1864. In one of these cases, the patient, a lady aged 24 years, who had slept for 40 days when she was 18 years of age, and 50 days when she was 20, at length had a sleep of nearly a year, viz., from Easter Sunday 1862 to March 1863. During this period, a false front tooth was removed in order to feed her with milk and soup, her only food. She was motionless and insensible. The pulse was low, the breathing scarcely perceptible, there were no evacuations, and she shewed no signs of leanness, her complexion remaining florid and healthy. In such cases as these, it is not a prolongation of healthy natural sleep that is present, but a condition of hysteric coma.

Again, there are certain states of the nervous system in which there is either an entire absence of sleep (and this may continue for many days, or even weeks) or incomplete sleeplessness. Complete sleeplessness is often a most important symptom of disease. It frequently accompanies certain forms of continued fever, inflammatory affections of the brain, the eruptive fevers, &c., and when it continues for many days and nights, delirium, followed by stupor, is very apt to supervene. When the wakefulness is unattended by any disorder sufficient to account for it, some serious disease of the brain is most probably impending, such as palsy, apoplexy, or insanity. Incomplete or partial sleeplessness is a symptom of far less grave import. It is of frequent occurrence in persons whose minds are much engaged, or whose occupations subject them to great mental exertion or to the vicissitudes of fortune. It is, moreover, a symptom of many chronic diseases, as gout, chronic rheumatism, skin-diseases, disorders of the urinary organs, dyspepsia, hysterica, &c. It may also be excited by certain beverages and articles of diet; thus green tea and strong coffee often occasion wakefulness, and a full meal of animal food late in the day often disturbs the sleep of persons accustomed to dine at an earlier hour.

In the treatment of sleeplessness, or *insomnia*, as it is usually termed by medical writers, the first indication is to remove the cause which occasions it, and 'more particularly to correct a close or contaminated air; to reduce the temperature of the apartment when it is high, and the quantity and warmth of the bedclothes; to remove all the excitants to the senses; to abstract the mind from all exciting, harassing, or engaging thoughts; and to remove or counteract the morbid conditions of which this is a symptom or prominent consequence.' —Copland's *Dictionary of Medicine*, art. 'Sleep and Sleeplessness.' A careful regulation of the secretions, by the due use of purgatives and alteratives, will often remove this symptom; and recourse should not be had to anodynes and narcotics until morbid secretions and fæcal accumulations have been completely got rid of. But these medicines are of great service when the system is thus prepared for their reception. The choice of the individual drug or combination of drugs must be dependent upon the peculiarities of the case, but, as a general rule, there is no more serviceable narcotic mixture for an adult than 25 or 30 minims of the solution of hydrochlorate of morphia (of the British Pharmacopœia), and 10 minims of chloric ether, taken in half a wine-glassful of water: medicines of this class should, however, never be resorted to without the advice of a physician.

SLEEP OF PLANTS, one of the phenomena of Irritability (q. v.) in plants. Light acts on plants as a powerful stimulus, essential to their active and healthful vegetation. When it is withdrawn, the flowers of many plants close, and the greater number shew a tendency to it, whilst leaves more or less decidedly incline to fold themselves up. The leaf-stalk also generally hangs down more or less, although in some plants it is more erect during sleep. The sleep of plants, however, is not always nocturnal. The flowers of some open and close at particular hours of the day. Thus, the crocus is a morning flower, and closes soon after mid-day; whilst some flowers expand only in the evening or during the night. Their hours of vegetative rest are probably as essential to the health of plants as those of sleep are to animals. It was Linnæus who first observed the sleep of plants in watching the progress of some plants of *lotus*, the seeds of which he had sown.

SLEEPERS, timbers laid *asleep* or resting along their whole length. They are chiefly used along the top of dwarf-walls for the support of the timbers of the ground floor of houses.—The timbers supporting railway rails, and laid at right angles to them across the railway, are also called sleepers.

SLE'SVIG, a duchy known till the 14th c. as South Jutland, formed part of the Danish dominions till 1864, when it fell into the hands of the Austrians and Prussians, and in 1866 was, with the duchy of Holstein, annexed to the kingdom of Prussia. The pop. in 1867 was 406,013. Within its old recognised limits, it was bounded on the N. by Jutland; on the E. by the Little Belt and the Baltic; on the W. by the German Ocean; and on the S. by Holstein, from which it was divided by the Eyder and the

* *The Physiology of Sleep*, in Guy's Hosp. Reports, Third Series, vol. 6, pp. 149—171.

Kiel Canal. The area was 3492 sq. miles. The country consists in its eastern and central parts of a gently undulating plain, deeply indented with fiords and streams; and on its western boundary of flat marshy tracts of ground, which require to be protected from the encroachments of the sea by numerous dams.

The numerous islands which skirt the west coast of S. have probably, at some not very remote period, formed part of the mainland, for navigation is so seriously impeded by the sandbanks, that this coast is now accessible for ships by only three passages. The cluster of small islands known as the Halligers, which lie, unprotected by dams, in the midst of these submerged sand-tracts, are so constantly exposed to the action of waves and storms, that the inhabitants are compelled to raise their houses on piles. On the eastern coast of S. lie the islands of Alsen, Aroe, and Femern, where the principal bays and inlets are the Haderslev and Aabenrade Fiords, opening into the Little Belt; the Flensborg Fiord, the Slie, the Eckernforde Fiord, and the Kieler Fiord, which formed the ancient boundary between S. and Holstein on the S.-E., while the Eyder completed it on the S.-W. The principal branches of industry are agriculture, the rearing of cattle, fishing, and ship-building. The Slie is the chief seat of the herring and salmon fisheries, which, although still of some importance, are very inferior to those of the middle ages, when, according to the Danish historian, Saxo Grammaticus, herrings were so plentiful in the Belts and Cattegat, that they could be caught with the bare hands. The chief towns of S. are Flensborg (q. v.), Slesvig, Haderslev (pop. 8000), Husum, and Tonder, neither of which has more than 5000 inhabitants. On the south frontier, and partly in Holstein, Rendsborg (pop. 11,000). S. has 800 country schools, diffused over every part of the duchy. With regard to the language spoken by the mixed population of the duchy, it may be asserted that rather more than the half speak Danish; and of the remainder, about 30,000 persons who belong to the islands on the western coast, which once formed part of the old province of North Friesland, still use the Frisic language, the rest of the inhabitants using either Low or High German. The original Danish element of S. has remained purest in the northern half of the duchy; while in the southern parts, where the inhabitants are naturally brought much in contact with Holstein, they have of late years adopted the views, tastes, and language of their German neighbours. The Lutheran is the established religion of Slesvig.

In accordance with the conditions stipulated in the treaty of Vienna, August 1864, by which the duchies of Holstein and S. were ceded to Austria and Prussia, the island of Aroe and other districts of S., measuring about 115 sq. m., were to be reunited to Denmark; while the latter power was to give in exchange a territory of about 130 sq. m., which, although situated within the boundary of S., had hitherto been under the jurisdiction of Jutland.

S., which forms part of the ancient Cimbrian Peninsula, has from the earliest period been a debatable land between Danes and Germans; and according to the authorities of the latter, it was anciently included in the Marches of the empire, having been incorporated by Henry the Fowler in 930, and reorganised by Otho I., when in 948 the latter erected bishops' sees in Aarhuus, Ribe, and Slesvig. In 1027, the Danish king Knud (our Canute) obtained from Conrad II. the recognition of the independence of S., which was declared to belong unconditionally to Denmark, and thenceforth given as a Danish fief of the crown to the younger sons of the regal house. In 1232, King Valdemar Seir, whose father, Prince Knud Laward, had ruled ably over the duchy, gave S.—which was then, and for some time later, known as South Jutland—to his younger son Abel. The exact terms of the donation became a subject of dispute during the successive reigns of Valdemar's sons, Eric, Abel, and Christopher, and began the long course of civil wars and family feuds which are associated with this much-contested territory. Abel, and his sons after him, backed by their kinsmen, the Counts of Holstein, maintained that Valdemar had given the duchy as an hereditary, inalienable, and indivisible fief; while, on the part of the Danish crown, it was contested that South Jutland was merely a *precarious* fief, which might be recalled at the pleasure of the sovereign. Its vicinity to Holstein tended to keep up the feuds, to which the vexed question of its mode of tenure had given occasion, and which, in fact, only ceased when the resources of the conflicting parties were exhausted, although the bitterness and ill-will with which they were fed seemed to know no intermission. The following brief summary gives the skeleton of the leading events of the history of S. from the dawn of its troubles till the final outbreak in 1848, when, by the influence of the neighbouring Holstein nobles, the Germanised great landed proprietors of S. entered upon the course of armed opposition to the mother-country, which culminated, in 1864, in the forcible separation from the Danish crown of the duchy of S., and its incorporation in the Prussian monarchy. In 1386, Queen Margaret (q. v.) gave S. in fief to Gerhard, Duke of Holstein; and on the extinction of his male heirs in 1459, it virtually lapsed to the crown, with which it was united in 1460 under the rule of Christian I. (the founder of the Oldenburg line), by a mode disastrous to the integrity of the Danish monarchy. See DENMARK. After frequent division among the younger members of the royal House, which gave rise to a great number of collateral lines of the Oldenburg family (of which the Glucksburg-Sonderborg and the Augustenburg are, with the exception of the imperial House of Russia and the ducal House of Oldenburg, the chief representatives), the ducal portions of S. were inalienably incorporated with the crown of Denmark under King Frederick IV. in 1721. This act, which had the guarantee of the great powers, had resulted directly from the treasonable attitude maintained in the previous wars with Sweden by the Holstein-Gottorp princes of S., and was ratified by Russia and Sweden, no less than by England and France. The different orders of the duchy took the oaths of allegiance for themselves and their heirs, the S. arms were quartered with those of Denmark Proper, and the duchy was included with the latter in one common mode of administration. In 1848, the revolutionary movement of continental Europe fanned the flame of discontent in the duchies into a blaze, and the upper classes of S., who had in the course of time become strongly imbued with the German tendencies of the Holstein nobles, with whom they fraternised, joined the latter in open armed rebellion under the chief leadership of the princes of Augustenburg. The Germanised S. nobles, influenced by the principles of hatred to Denmark, which had long been gathering strength in the university of Kiel, refused to admit the difference between their relations to the crown and those of the Holsteiners, with whom they demanded to be indissolubly associated in separate legislative and executive chambers. The king refused to separate S. from the monarchy; the irritation increased on both sides; the royal troops appeared in the duchies to restore order;

the S.-Holstein army, whose ranks were principally filled by German volunteers, took the field, aided by the confederate forces sent by the Diet to co-operate with the Holsteiners. The troubles by which the German states were threatened at home led, after a few indecisive engagements had been fought, to the withdrawal of the confederate armies, and Prussia having made a special treaty of peace (after a preliminary truce with Denmark), the duchies were left to themselves, and the royal authority re-established, on the understanding that the king should submit a new form of constitution for Holstein and S. to the Diet, on account of the former being a member of the Confederation; S. being in the meanwhile put under a provisional government of Danish, Prussian, and English commissioners. By the peace with Prussia, it was solemnly guaranteed that all old treaties, including that of 1721, should be maintained in regard to Denmark; and in 1851, Austria threw an army into the duchies to aid Denmark in supporting her authority, and in dissolving the joint S. and Holstein assembly. On the death of Frederick VII. in 1863, Prince Christian of Glucksburg (see DENMARK), having ascended the throne as Christian IX., king of Denmark, Prince Frederick of Augustenburg called upon the S.-Holstein authorities to refuse the oath of allegiance to the new king, and to acknowledge himself as the rightful duke of S.-Holstein, basing his claims on his descent from the legitimate and elder male line of the House of Oldenburg. This appeal was responded to by 25 members of the Holstein Diet, who, on behalf of their own duchy and of S., petitioned the German Diet to recognise the validity of the claims of the Augustenburg line, and to pronounce the London protocol of the act of succession devoid of force. The Prince, by this step, set at nought the family compact by which his father, uncle, and himself, for themselves and their heirs, had, at the close of the war of 1848, accepted a sum of money as full indemnity for all claims on the Danish territories, and been allowed on that condition to evade all further consequences of the open rebellion in which they had stood against the throne. In the meanwhile, the fundamental law of November 1863 for the kingdom of Denmark and the duchy of S., which had passed the Rigsrad, and received the late king's signature shortly before his death, was published, together with a manifesto of Christian IX., stating his intention in regard to Holstein and Lauenburg. The Diet, without committing itself to uphold the Augustenburg claims, put a confederate execution into Holstein; the Danish troops were withdrawn into S.; and on the 6th January 1864, the Holstein towns did homage to the duke; while a Federal commission suppressed the provisional Holstein government, which had exercised its powers since 1862, and established a ducal government at Kiel. The Austrians and Prussians, professing to act for the Diet, summoned the Danish king to withdraw the constitution of November within 48 hours; in reply to which the Danish government demanded a term of six weeks to convoke the Rigsrad, without whose sanction no constitutional change could be adopted. The demand was rejected, and the Austro-Prussian army entered Holstein, and hostilities commenced. For ten weeks the Danes made a gallant stand against their enemy, whose enormous superiority in strength of numbers, and in the efficiency of their artillery and small-arms, made their final victory the inevitable rather than the glorious result of the campaign. The Danes were compelled to suspend hostilities, and to submit to the terms dictated by their conquerors. A conference was held at Vienna, and after protracted negotiations, Denmark was constrained to accept peace (August, 1864), on the hard terms of ceding to Austria and Prussia, Holstein, S., and Lauenburg, on the ground that the indivisibility of the two duchies must be firmly established for the German fatherland by these two great powers. For some time afterward, Duke Frederick of Augustenburg was in turn the favoured and the rejected candidate for the throne of the new state of S.-Holstein. The upper classes in small numbers in S. and in Holstein were almost unanimously in favour of his claims, while the burgher and lower classes of S. appeared equally unanimous in regretting their severance from Denmark; and the decidedly expressed wishes of the Holstein party, backed by the lesser German states, to have the duke as their sovereign, the protests and counter-protests of the Diet and of foreign powers, resulted in an announcement by Austria and Prussia, that, according to the evidence of the commission appointed to examine the merits of the various claims of Denmark, Augustenburg, and Oldenburg to the duchies, Christian IX. was by right of succession the undoubted possessor, and that from him the duchies had passed by right of victory to Austria and Prussia. This extraordinary solution of the S.-Holstein question was ratified at Gastein (August, 1865), in a treaty between Austria and Prussia, in which, without regard to the German or Danish proclivities of Holstein or of S., the former duchy was transferred to Austria, and the latter to Prussia, the garrisons and forts to be manned at the pleasure of the contracting parties. Austria soon after made over to Prussia the rights acquired by the war over the duchy of Lauenburg for the sum of two and a half million Danish dollars. The war between Prussia and Austria, which broke out in 1866, had the effect of bringing the whole of the territory of Slesvig and Holstein under the sway of Prussia, of which kingdom it now forms a province.

SLI'CKENSIDES are the smooth and polished, and generally glazed surfaces of flaws in rocks. They are considered to have been produced by the friction of the two surfaces during some movement of the rock. But the two surfaces of the flaw are almost always so uneven that it is impossible to conceive that they could have rubbed against each other; besides, the flaws are generally very small, and the true slickenside is always confined to a single stratum, never passing into the bed above or below. We believe they are the castings of liquids or gases confined in the bed, and subjected to great pressure, and are similar in origin to the glazed cavities produced by gases in slags, or, to use a very familiar illustration, by the compressed steam in breakfast rolls.

SLIDING RULE, an instrument invented by the Rev. William Oughtred, an English divine and mathematician, for the purpose of solving arithmetical problems mechanically, consists of three pieces of wood, of which two are fastened together by slips of brass at a sufficient distance from each other to permit of a third sliding between them. The size of instrument which best combines convenience with accuracy is one about 2 feet long, 2 inches broad, and $\frac{1}{4}$ inch thick. One side of the rule has the following scales marked on it in order: a line of tenths of inches, of equal parts divided into tenths and hundredths of feet; three lines of numbers, each line consisting of the numbers from 1 to 10 twice repeated; a line of sine rhumbs (logarithmic sines of each quarter-point of the compass); a line of meridional parts; and a line of equal parts. Of these, two of the lines of numbers are on the middle piece or *slider*. On the other side are—two lines of *natural scales*, including sines, secants, tangents, equal parts, &c.; two lines of logarithmic sines,

two lines of logarithmic tangents, a third line of logarithmic sines, and a line of versed sines. Of these, one line of logarithmic sines and one of tangents are upon the slider. The scale in most common use is that of numbers, and a description of the way in which it is used will give a key to the whole working of the instrument. It is necessary, however, to notice as a preliminary, that the scale of numbers is not evenly divided, as in this case only addition and subtraction could be performed, but is divided in proportion, not to the numbers, but to their logarithms, so that 3, whose logarithm is very nearly the half of that of 10, stands almost halfway between 1 and 10; and similarly of the other numbers. All questions of numerical proportion can thus be easily worked by means of the line of numbers on the slider, and the adjacent and corresponding one on the fixed part of the rule. To find a fourth proportional to three given numbers, we place the first term (on the slider) opposite to the second term (on the fixed scale), and opposite the third term (on the slider) is the fourth or number required (on the scale). Multiplication is performed by making 1 the first term of a proportion, and division by making it the second or third. The other scales marked on the rule are useful in the solution of trigonometrical, geographical, and nautical problems, and the results obtained are much more accurate than one at first sight would believe. Sliding rules of circular form have been made by the French, but they are not in any way preferable to the ordinary straight form.

SLIDING SCALE, a provision in some of the statutory restrictions formerly in force on the trade in corn, by which, in order to encourage importation when prices were high, and discourage it when low, the import duty was diminished as the price rose, and at famine-prices grain came in duty free. By the act of 1828, wheat was allowed to be imported on payment of a duty of £1, 4*s.* 8*d.* when the average price over England was 62*s.* a quarter. For every shilling less of price, a shilling was added to the duty; and for a rise of price the duty decreased. In 1842, while the agitation regarding the corn-laws was going on, Sir Robert Peel introduced and carried a modification of the Sliding Scale, which, however, did not succeed in mitigating the popular hostility to the corn-laws. By the Sliding-scale Act of 1842, the duty per quarter was fixed at £1 when the price of corn was under 51*s.*, and diminished as the price increased, till on the quarter of wheat attaining the price of 73*s.* it fell to 1*s.* See CORN LAWS.

SLI'GO, a maritime county of the province of Connaught, Ireland, bounded on the N. by the Atlantic and the Bay of Donegal, S. by Roscommon and Mayo, E. by Roscommon and Leitrim, and W. by Mayo. It is 41 miles from east to west, and 38 from north to south; the total area comprising 461,753 acres, of which 290,696 are arable, while 151,723 are uncultivated. The pop. in 1861 was 124,845, of whom 112,436 were Roman Catholics, and 10,438 Protestants of the Established Church.

The coast-line is very irregular, and indented with numerous bays, and, except in the Bay of Sligo, is rocky and dangerous for navigation. The surface rises gradually from the coast eastwards as far as an elevated range called Slieve Gamph and the Ox Mountains, the highest point of which rises to 1800 feet. S. contains comparatively few and unimportant lakes, but some of these, however, are extremely picturesque, especially Lough Arrow and Lough Gill. Only three of its streams are navigable —the Moy, the Owenmore, and the Garrogue, and they are all inconsiderable. The county is traversed by a railway, which is a branch of the Midland Great Western, and connects the county town of Sligo (q. v.) with Dublin. The mineral products of the county, although not very rich, are various, and consist of copper, lead, iron, and manganese. The climate is variable, and although rain is frequent, it is, on the whole, mild and healthy. The soil in the north is mossy and sandy, both being occasionally intermixed, and at times alternating with a gravelly loam. The plain of S. is a deep rich loam; and in the southern portion of the county are found large tracts of corn-land and pasturage. The occupations of the people are mainly agricultural, and, until some years back, they were chiefly engaged in tillage; but the land is now chiefly used for pasturage. The number of acres under crops of all kinds in the year 1862 was 103,301. The cattle in that year numbered 76,226; sheep, 44,717; and pigs, 18,062. The number of holdings ten years before 1852 had been 13,992, which is now somewhat reduced. The extent of coast-line has led a considerable number of the population to engage, at least partially and occasionally, in fishing. The S. fishery district comprises 112 miles of coast, and keeps engaged upwards of 200 registered vessels, employing more than 1200 men and boys. The principal towns are Sligo (q. v.), Ardnaree, and Tobercurry. The number of pupils attending the national schools throughout the county in 1864 was 8734, distributed over about 100 schools.

S. was anciently the seat of the O'Connors, and was the scene of many conflicts between the several branches of that family. The domestic feuds of the O'Connors were among the causes which facilitated the first inroads of the Anglo-Normans. The district contains many remains both of the Celtic and of the Anglo-Norman period. Of the former, there is one very interesting called the Giant's Cairn, near Sligo; and there are many raths, cromlechs, and ancient caverns. The county of S. sends two members to the imperial parliament.

SLIGO, chief town of the county of the same name, situated on the river Garrogue; distant from Dublin, with which it is connected by a branch from the Midland Great Western Railway, 131 miles north-west. The pop. in 1862 was 10,420; of whom 8242 were Roman Catholics, and 1557 Protestants of the Established Church. S. had its origin in the erection of a Dominican abbey in the 13th c. by Maurice Fitzgerald, Earl of Kildare, around which —and a castle also built by him—a town was gradually formed. In the reign of James I., it received a charter. The modern town stands within a bend of the river, chiefly on the left bank. It is for the most part well built, and contains several handsome public edifices. It possesses few important manufactures, but is a place of considerable commerce, which is directed with judgment and energy by a body of town and harbour commissioners. In 1863, 772 vessels, of 123,349 tons, entered and cleared the port. The exports are chiefly of corn, flour, meal, butter, provisions, and yarn. Steamers ply regularly between S. and Glasgow. The borough returns one member to the imperial parliament.

SLING, a weapon much in use before the introduction of firearms, consisted of a piece of leather, with a round hole in the middle, and two cords of about a yard in length. A round pebble being hung in the leather by the cords, the latter were held firmly in the right hand, and swung rapidly round. When the stone had attained great speed, one string was disengaged, on which the stone flew off at a tangent, its initial velocity being the same

Vol. VIII., page 772. SLOTH

as it had at the last moment of revolution. This velocity gives far greater range and force than could be imparted in mere throwing.

SLIP, in a Dockyard, is a smooth, inclined plane, sloping down to the water, on which a ship is built. It requires to have a very solid foundation. Among modern inventions is a slip on which a sort of truck runs on numerous rails. This truck is run under a ship as she floats; the water is diminished till she rests on it, and it is then hauled up the slip by steam power until she is high and dry. Such a slip takes the place of a dry dock. See also LAUNCH and SHIP-BUILDING.

SLIPPED, in Heraldry, a term of blazon applied to a leaf, branch, or flower, which is represented with a stalk, and torn from the parent stem.

SLOANE, SIR HANS, an eminent physician and naturalist, of Scotch parentage, his father having been the chief of the Scottish colony which was settled in Ulster by James I. of Great Britain, was born at Killyleagh, in County Down, Ireland, 16th April 1660. He devoted himself during his boyhood to natural history and medicine, and in spite of an attack of hæmoptysis, which lasted from his 16th till his 19th year, he arrived in London in 1679, with an excellent knowledge of the first of these sciences, and a fair acquaintance with the second. His apprenticeship to Stafforth, a pupil of Stahl (q. v.), and the acquaintance, subsequently ripened into close friendship, which he formed with Boyle and Ray, two of the most celebrated naturalists of their time, did much to encourage and advance him in his favourite studies. During a brief sojourn in France, he attended the lectures of Tournefort and Du Verney, obtained on his return, by the active support of Sydenham (q. v.), a footing in London as a physician, and was elected a member of the Royal Society in 1685, and of the Royal College of Physicians in 1687; but in September of the latter year, he accompanied Monk, Duke of Albemarle, to Jamaica, and investigated the botany of that and the adjoining islands with such zeal and diligence during the 15 months of his stay, that his herbarium numbered 800 species. Resuming his professional practice on his return, he became physician to Christ's Hospital (1694—1724), President of the College of Physicians (1719—1735), Secretary to the Royal Society (1693), Foreign Associate of the French Academy of Sciences (1708), and succeeded Sir Isaac Newton as President of the Royal Society in 1727. He had been created a baronet and physician-general to the army in 1716; and in 1727 received the further honour of being appointed royal physician. Though of remarkably delicate constitution, he lived to the great age of 92, dying at Chelsea, 11th January 1753. The chief point to be remarked in S.'s moral character was his benevolence, as shewn in the charitable uses to which he applied the whole of his salary as physician of Christ's Hospital, in his zealous promotion of the various schemes for affording medicine and attendance gratuitously to the poor, and his support of the Foundling Hospital, of which he was one of the founders. By long-continued perseverance, he succeeded in forming a most extensive museum of natural history, a library of 50,000 volumes, and 3560 MSS., which he directed to be offered at his death to the nation for £20,000 (about one-fourth of its real value), and which formed the commencement of the British Museum (q. v.). He also contributed numerous memoirs to the *Philosophical Transactions*, whose publication he superintended for a number of years. But his great work was the *Natural History of Jamaica* (fol. 1707—1725), containing also an excellent account of the topography, meteorology, and population of the island, which book was the means of introducing into the Pharmacopœia a number of excellent drugs, hitherto unknown.

SLOBDO'SK, or SLOBODSKOI', a town of Russia, in the government of Viatka, is situated on the river Viatka, about 16 miles north-east of the town of the same name. Pop. 5914.

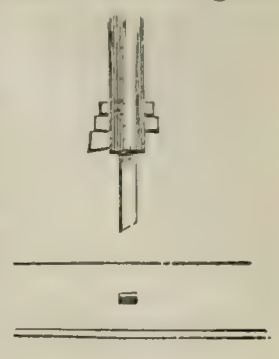
SLOE, or SLOE-THORN (*Prunus spinosa*), a shrub of the same genus with the plum, and perhaps really of the same species with it and the bullace. It is generally a shrub of 4—10 feet high, sometimes becoming a small tree of 15—20 feet. It is much branched, and the branches terminate in spines. The youngest shoots are covered with a fine down. The flowers are small, snow-white, and generally appear before the leaves. The fruit is ovate, or almost globose, pale blue with blackish bloom, and generally about the size of the largest peas. The S. is abundant in thickets and borders of woods, and in arid places in Britain and almost all parts of Europe. The shoots make beautiful walking-sticks. Although spiny, the S. is not suitable for hedges, as its roots spread, and it encroaches on the fields. The bark is bitter, astringent, and tonic. The flowers, with the calyx, are purgative, and are in some places much used as a domestic medicine. The leaves are used for adulterating tea. The unripe fruit dyes black. The fruit is very austere. It is much used on the continent of Europe for making a preserve, also in some places for making a kind of brandy. An astringent extract, called *German Acacia*, is prepared from it, which was once much employed in cases of diarrhœa and mucous and bloody discharges. The juice is much used to impart roughness to port wine, and in the fabrication of spurious port.

SLO'NIM, a town of Russian Poland, in the government of Grodno, and 72 miles south-east of the town of that name. It has large manufactures of cloth. Pop. 10,021.

SLOOP is a one-masted cutter-rigged vessel, differing from a cutter, according to old authorities, in having a fixed bowsprit and somewhat smaller sails in proportion to the hull. The terms 'sloop' and 'cutter' appear, however, to be used nearly indiscriminately. In the British navy, a sloop-of-war is a vessel, of whatever rig, between a corvette and a gun-boat, and ordinarily constituting the command of a commander. In the days of the sailing navy, sloops-of-war carried from 10 to 18 guns; but, with the introduction of steam, the number of guns has ceased to be distinctive.

SLOPS, in the Navy, are somewhat more extensive than 'necessaries' in the army. They comprise the clothes and bedding of a sailor. Within certain limits, government, acting through the ship's paymaster, supplies the men with slops at cost price. When a sailor dies, his slops are sold by auction for the benefit of his representatives.

SLOTH (*Bradypus*), a genus of mammalia, of the order *Edentata*, and family *Tardigrada*. The name was given from observation of the very slow and awkward movements of the animals of this genus on the ground; but a better acquaintance with their habits, and observation of their movements among the branches of trees, for which their conformation peculiarly adapts them, have shewn it to be by no means appropriate or descriptive. In like manner, Buffon's notion that they are creatures of imperfect organisation, and doomed to a miserable existence, has been completely exploded. Their structure, like that of every other creature, is admirably



adapted to their mode of life. They feed on the leaves, buds, and young shoots of trees, amongst the branches of which they are born and spend their whole life, rarely and unwillingly descending to the ground. They do not walk upon the branches, but cling beneath them, with the back downwards. The fore-legs are much longer than the hinder ones, and are used for embracing a branch, or for drawing in the branches on the foliage of which they are to feed, and both the fore and hind feet are furnished with very long, curved, and sharp claws. The pelvis is very wide; and the hind-legs, thus widely separated, also diverge from one another. The structure of the wrist and ankle-joints is such that the palm or sole is turned towards the body, so that upon the ground, the animal is compelled to rest on the side of the hind-foot, whilst the length of the fore-legs causes it to rest on the knee or elbow of them, struggling forward by a shuffling movement, and dragging itself along by stretching out the fore-legs alternately and hooking the claws into the ground, or grasping some object. But in a dense tropical forest, sloths generally find it easy to pass from the branches of one tree to those of another, often taking advantage for this purpose of a time when branches are brought within their reach by the wind. Where the trees are more distant from each other, they will eat up the whole foliage of a tree ere they descend from it. The hair of sloths is coarse and shaggy, of a very peculiar texture, inelastic, and much like grass

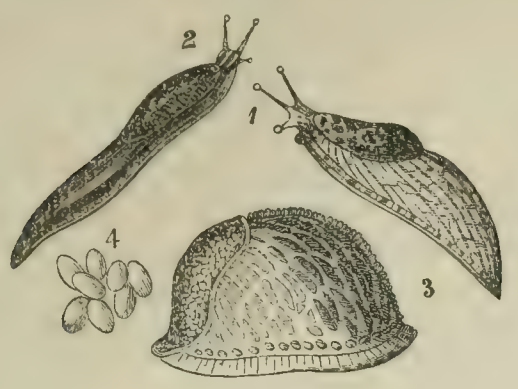
Three-toed Sloth (*Bradypus trydactylus*).

withered in the sun, but affords an excellent protection from insects, whilst it also gives them such an appearance that they are not readily observed except when in motion. The muzzle of sloths is short, and the tail is short. There are no incisor teeth, but sharp canine teeth, and eight molars in the upper, six in the lower jaw. The molars are cylindrical, penetrated by no laminæ of enamel, and adapted merely for crushing, not for grinding the food. For this, however, there is compensation in the stomach, which is somewhat imperfectly divided, by transverse ligatures, into four compartments, for the longer retention and more thorough digestion of the food, although there is no rumination. The female sloth produces only one young one at a birth, which clings to its mother till it becomes able to provide for itself. The voice of sloths is a low plaintive cry. Their chief enemies are large snakes, but against these they defend themselves by their powerful fore-legs and claws. A sloth has been known to grasp a dog round the neck and strangle it. There are very few species. One species has the fore-feet furnished with only two toes: the others have three. These, with other differences, have been made the ground of a recent division of the genus into two. The Two-toed S., or Unau (*Bradypus* or *Cholœpus didactylus*), is about two feet in length, of a uniform grayish-brown colour, often with a reddish tint. The best-known species of Three-toed S. is the Ai (*Bradypus* or *Acheus tridactylus*), which is smaller than the Unau, has a more obtuse muzzle, and is generally brownish gray, slightly variegated with hairs of different tints, the head darker than the body. All the sloths belong to the tropical parts of America.

SLO'TTING-MACHINE, a machine for cutting slots, or square grooves, in metal. It is of great importance in mechanical engineering, and many very ingenious inventions have been made for facilitating the process. The principle is, however, very simple, and is the same in all. It consists of a cutting tool, or chisel, held very firmly in an arm, which is pressed down and raised alternately. The tool is thus made to pare off a thin portion of the metal each time it descends, until it has cut a slot of sufficient size. Water is continually thrown on, to prevent the metal from becoming overheated by the friction.

Slotting-machine.

SLOUGH, a village of England, in the county of Buckingham, 18 miles west of London, by the Great Western Railway. On the road between S. and Windsor, which is distant about two and a half miles, lived Sir William Herschel, and at the observatory which he erected here, in which was placed his great telescope, many of his important astronomical discoveries were made. Pop. (1861) 3425.



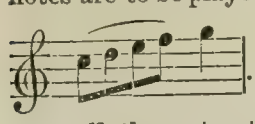
SLOVAKS, The, are the Slavic inhabitants of North Hungary, who, in the 9th c., formed the nucleus of the great Moravian kingdom, but who, after the bloody battle of Presburg (907 A. D.), were gradually subjugated by the Magyars, to whom even yet they bear no friendly feeling. Their number is reckoned at 2,750,000, of whom 800,000 belong to the Protestant, the rest to the Catholic Church. The S., whose character probably comes nearest to that of the old Slavic type, travel in great numbers over Germany and Poland as pedlars. Their language is a dialect of Bohemian. Among the most notable of the Slovak authors are the poets Holly and Kollar (q. v.); Matth. Bel (1684—1749); Stephan Leschka (1757—1818), editor of the first Slovak journal; Bernolak, author of a Slovak grammar; Palkovitsh (died 1835); and Tablitsh, who published four volumes of poetry (1806—1812). A fine collection of popular Slovak ballads has been published by Kollar (2 vols., Ofen, 1834).

SLOW-MATCH, a combustible material, such as cotton, hemp, tow, &c., often dipped in a solution of nitrate of potash (saltpetre), and formed into a thin rope. It is used for exploding gunpowder in various ways, on account of its slow, steady way of burning, a sufficient length being taken to enable the operator to remove to a safe distance before the explosion. Slow-match was much used by artillerymen for firing of cannon, but it has generally given way to friction fusees and percussion caps.

SLUBBING. See Spinning.

SLUG (*Limax*), a genus of gasteropodous molluscs of the division *Monœia* (hermaphrodite), and of the family *Limacidæ*, which is closely allied to the snail family, *Helicidæ*, but has no external shell. There

is, however, a rudimental shell, generally concealed within the mantle, placed over the respiratory cavity. The *Limacidæ* are diffused over the whole world. They commit great ravages among field and garden crops during moist weather. In frosts, they become



Slugs.

1. Gray slug; 2. Black slug; 3. The same full grown, and as it appears when at rest; 4. Its eggs.

dormant, taking shelter under clods and at the roots of plants. They lay eggs in clusters, in moist places, often at the roots of grass. The eggs resemble small oval bags of jelly. The body is generally oval or oblong, elongated. The foot is not distinct from the body. There are four retractile tentacles; the eyes are at the tips of the longer pair. Slugs often climb trees in quest of decaying vegetable matter on which to feed, and let themselves down by means of mucous threads, for the formation of which there is a small aperture at the hinder end of the body. Of British species, one of the most common is the Gray S. (*Limax agrestis*), which is of a whitish ash colour; another is the Great Gray S. (*L. maximus* or *antiquorum*), the largest British species; another is the Black S. (*L. ater*), often popularly called the Black Snail. The Red S. (*Agrion agrestis*) is also very plentiful. Careful gardeners often gather slugs by the aid of a lantern at night, and destroy them. They may also be killed by watering the ground with a weak solution of ammonia.

SLUR, in Music, an arch drawn over two or more notes *not* on the same degree, to indicate that these notes are to be played *legato*, or smoothly and fluently

. In vocal music, a slur is placed over all the notes that are to be sung to the same syllable, unless where they are grouped together by a common line. A slur must be distinguished from a *tie*, which is a similar arch drawn over two notes on the same degree, and denoting that instead of the two notes written, one is to be played of the length of both.

SLUTSK, a town of Russian Poland, in the government of Minsk, about 63 miles south of the town of that name, near the source of the Lesser Slutch. With the exception of its public buildings, the houses are almost entirely of wood. Pop. 8226.

SMACK is a generic term for small decked or half-decked vessels employed in the coasting and fishing trade. The majority of smacks are, however, rigged as cutters, sloops, or yawls. According to Wedgewood, the *m* in this word is a corruption of *n*; the Anglo-Saxon has *snakk*, a small vessel, and there is a corresponding form in the other Teutonic and Scandinavian tongues.

SMALL-ARMS, in the modern acceptation, consist of the weapons actually carried by a man. They have been described under their respective heads, Bayonet, Firearms, Lance, Sword, Pistol, &c.

SMALL-ARMS FACTORIES, Royal, are the establishments through which all the small-arms of every description are supplied to the regular army, the militia, yeomanry, and volunteers. The headquarters are at Enfield, where there is a vast manufactory; at Birmingham, there is a considerable establishment for viewing the arms supplied by contractors; and at Pimlico there is a factory for repairing damaged arms, and for training armourer-sergeants for detached service with regiments. For many years, there had been a small ordnance factory at Enfield Lock, where a few thousand muskets were laboriously forged by hand each year; but when the sudden introduction of the rifle, and the demands of the Russian war, called for a supply of arms, which the trade of all Europe and America was unable to meet, government determined to erect machinery for the fabrication of arms. For this purpose, the factory at Enfield was entirely remodelled; machinery of great power and delicacy was adopted, and now, when in full work, the factory can turn out daily 1000 complete and proved rifles, besides a corresponding complement of other small-arms. At the same time, the accuracy of workmanship is so great, that a hundred rifles might be taken entirely to pieces, the several portions thrown promiscuously together, and a hundred complete rifles could be instantly re-formed without any difficulty from the same pieces. Much of the merit of this great establishment is due to Colonel Manley Dixon of the Royal Artillery, who has superintended the factory since it has been remodelled. The success of the factory has reduced in a remarkable degree the cost of rifles, and has brought down correspondingly the price charged by the trade for the large quantities still intrusted to it.

The cost of the factories, when in full operation, is of course considerable. In the year 1865, when the demand for small-arms was small, the annual charge was only £172,974.

SMALL DEBTS is a phrase current in Scotland to denote debts under £12, recoverable in the Sheriff Court. See Sheriff. In England, the same debts are recoverable in the County Court (q. v.).

SMALLPOX, or VARI'OLA, is one of the most formidable of the class of febrile diseases known as the *Exanthemata* (q. v.). All cases of regular smallpox are divisible into three stages—viz. (1), that of the initial or eruptive fever; (2), that of the progress and maturation of the specific eruption; and (3) that of the decline. Some writers make a primary stage of the period of incubation, or of the time intervening between the reception of the poison into the system, and the first appearance of febrile symptoms; but this is not entitled to be regarded as a stage of the disease, seeing that no symptoms of disorder have begun to shew themselves. The *first stage* begins with rigors, followed by heat and dryness of the skin, a quickened pulse, furred tongue, loss of appetite, pain in the pit of the stomach, with nausea, vomiting, headache, and often pains in the back and limbs. The violence of the pains in the back, and the obstinacy of the vomiting, are frequently very well marked and characteristic symptoms. In children, the disease is often ushered in by convulsions; while delirium sometimes attends its outset in adults. On the third day, minute red specks begin to come out first on the face, then on the neck and wrists, and on the trunk of the body, and lastly, on the lower extremities. The fever usually begins to subside as soon as the eruption appears, and by the

beginning of the fifth day, when the eruption is generally completed, the fever has entirely disappeared. The *second stage* commences when the eruption is fully out. Upon the second or third day of the eruption, a little clear lymph is seen in each pimple, which has increased considerably in size since its first appearance, and which is thus converted into a *vesicle*. The vesicles gradually increase in breadth, and become converted into *pustules*, which are at first depressed in the centre, but by the fifth day of the eruption become turgid and hemispherical; the suppuration on the face being complete by about the eighth day from the commencement of the fever, and the same process rapidly following in the other parts of the body in the same order of succession as that in which the eruption originally appeared. The pustules then break, and scabs or crusts form over them, which usually fall off after four or five days' existence. The number of pustules in any special case and the severity of the disease, stand in a direct ratio to one another; for 'the number of pustules indicates, in the first place, the quantity of the variolous poison which has been reproduced in the blood; and, in the second place, it is also a direct measure of the extent to which the skin suffers inflammation. Sometimes there are not more than half-a-dozen pustules; sometimes there are many thousands. If all these were collected into one, it would be an enormous phlegmon. For both these reasons, the system suffers commotion, distress, and peril, in proportion to the quantity of the eruption.'—Watson's *Lectures*, &c., 4th ed. vol. ii. p. 857. The progress of the pustules is usually accompanied with swelling of the skin of the face, with a painful sensation of heat and tension; the scalp is often swollen; soreness of the mouth and salivation usually supervene; and the patient exhales a peculiar and disagreeable odour. About the eighth or ninth day of the disease, a recurrence of the fever, known as 'the fever of maturation,' sets in with varying degrees of intensity, according to the number and arrangement of the pustules. When the pustules are numerous, they run together; when they are few, they keep separate. Hence the division of smallpox into the two great varieties of *distinct* and *confluent*, or *variola discreta* and *variola confluens;* and this division is of the highest importance, because the distinct form of the disease, in which the pustules are isolated, is scarcely ever dangerous; while the confluent form, in which they coalesce, is never free from danger. The *third* or *declining stage* is, in the distinct variety, little more than a period of convalescence. About the eleventh or twelfth day, the pustules on the face become brown and dry at the top, or some of them break, and the fluid which oozes out solidifies into a yellowing crust; and from this time the process of *desiccation* goes on, the swelling of the face subsides, and at last only dry scabs remain, which gradually fall off about the fourteenth day. It is not till three or four days after the scabs have formed on the face, that the same process is completed over the whole body. The scabs are usually completely gone by the twenty-first day, leaving behind them blotches of a reddish brown colour, which sometimes continue for some months before they quite disappear; and some of the pustules, in consequence of ulceration of the true skin, leave pits, especially on the face, which remain permanently. The period of scabbing is accompanied by various symptoms of improvement: the tongue becomes clean, the appetite returns, and by the time that the scabs have fallen off, the patient may be regarded as restored to health; so that the entire course of a case of distinct or discrete smallpox occupies about three weeks. In the confluent form of the disease, the eruptive fever is more violent, the pain in the back is more severe, and the sickness more obstinate, and the eruption comes out earlier and less regularly than in the distinct variety which we selected for description as representing the more natural course of the disease. Moreover, the pustules do not fill so completely, nor are they of the normal yellow purulent hue, being whitish, brown, or even purple. But the most important difference between the two forms is in the *secondary fever*, which sets in when the pustules are mature. This fever, which is slightly marked in distinct smallpox, is usually intense, and highly dangerous in the confluent form; and it is at this period of the disease that death most commonly occurs. Statistics shew that the eighth day of the eruption is the most perilous *day*, and the second week the most perilous *week*. The early occurrence of death—that is to say, during the first week—denotes a peculiar malignancy in the disease. 'The nervous system,' says Dr Watson, 'appears to be overwhelmed by the force of the poison. During the second week, the disorder proves fatal chiefly in the way of apnœa; from some affection of the respiratory passages. After that period, the characters of asthenia commonly predominate, the patient sinks under some casual complication, or the powers of life are gradually worn out by so much irritation of the surface, and so large an amount of suppuration.'—*Op. cit.*, vol. ii. p. 860.

The above are the essential symptoms of smallpox, both in the distinct and confluent form. This disease is, however, often accompanied by other symptoms, which we have merely space to name; such as sore throat (which often depends upon pustules situated there), salivation, and (in the confluent form, during the secondary fever) erysipelatous inflammation, leading to the formation of abscesses, glandular swellings, sloughing sores on the sacrum, &c. In pregnant women, the disease often causes abortion, which is most commonly followed by death. The dead child occasionally, but not often, is covered with pustules.

The *cause* of smallpox is universally allowed to be a specific contagion, of whose nature we are in the most profound ignorance. There is probably no disease so contagious as this. Dr Haygarth stated (in 1793) that, during his long attention to this subject, not a single instance has occurred to prove that persons liable to smallpox could associate in the same chamber with a patient in the distemper without receiving the infection; and he was informed by an American physician of an instance in which the poisonous effluvium crossed a river 1500 feet wide, and affected ten out of twelve carpenters who were working on the other side. The contagion acts either through the air, or by contact with the skin, or by inoculation; and the disease may be caused by the dead body, even when it has not been touched. What products of the diseased body are contagious, is not exactly known, but the contents of the pustules and the dried scabs certainly are so. Opinions are divided as to the period at which the disease begins and ceases to be contagious. It is safest to maintain that it is capable of self-propagation as soon as the febrile symptoms have exhibited themselves. How soon the patient ceases to be dangerous, cannot be decided with accuracy; but the stability of the contagious principle may be inferred from the fact, that clothing will retain it for months, and it is said for years, when confined. Like all the contagious exanthemata, smallpox appears in an epidemic form, at irregular, and, in our ignorance, it would almost seem capricious intervals. After an extraordinary exemption, perhaps

for years, a district is suddenly invaded by it, and continues to suffer for a longer or shorter period, after which the disease spontaneously disappears—dies out, as it were—and does not reappear perhaps for years. Different epidemics vary very much in their severity, and isolated cases are usually milder than those occurring when the disease is epidemic. Race has much to do with the severity of the disease; the constitution of the dark races, the Negro and the Red Indian, being singularly susceptible of the contagion, and exhibiting very little power of resisting the fatal tendency of the disease.

It is universally admitted that the discovery of *Vaccination* (q. v.), by which smallpox is deprived of its danger, is the greatest triumph of modern medicine. *Inoculation* (q. v.) protected the individual, but increased rather than diminished the total number of deaths, while vaccination has the advantage of protecting both the individual and the community. Although, in the great majority of cases, vaccination affords perfect protection against smallpox, it not very unfrequently happens that vaccinated persons, when exposed to the contagion of smallpox, get the disease in a modified form, milder and shorter even than after inoculation, and therefore incomparably milder than in the natural form. The disorder occurring under these circumstances, has received the various names of *modified* or *post-vaccinal* smallpox, or the *varioloid* disease. As Dr Wood observes: 'It is impossible to describe minutely all the shapes which the varioloid disease assumes. There is every shade between the slightest symptoms, scarcely recognisable as having affinity with smallpox, and the nearest possible approach to the regular disease.'—*Practice of Medicine*, 4th ed., vol. i. p. 380. In whatever form the varioloid disease appears, it wants the peculiar odour of smallpox, and secondary fever is very rare. The constitutional disturbance which, for the first week, may have been as severe as in the true disease, usually subsides entirely when the eruption has reached its height, and the patient is convalescent at the period when, if he had not been vaccinated, he would have been in the greatest danger.

With regard to prognosis, it may be stated generally, it is a very fatal, and was formerly an extremely destructive disease—one death occurring in every four cases. Modified smallpox is very seldom fatal, although instances of death are occasionally reported. Smallpox is more fatal at the two extremes of life than in the intervening period, and, as has been already noticed, is especially dangerous in pregnancy. In olden times, it was believed that the eruption was an effort of nature to get rid of the noxious matter, and hence heating and stimulating measures were adopted with the view of promoting the eruption. To Sydenham (q. v.) belongs the credit of first recommending an entirely opposite or cooling mode of treatment; but his suggestions met with the most severe opposition, and it was not till long after his death that the cooling treatment was fairly established. In mild cases, and in cases of varioloid disease, the physician has merely to guard the patient against hurtful influences, such as stimulating foods or drinks, too hot a room, or improper exposure to cold, and to prescribe cooling drinks during the fever, and occasional laxatives if they shall be required. In more severe cases, the fever may be combated by saline purgatives, prescribed so as to produce two or three liquid stools daily, and by free ventilation of the surface of the body. When the eruption is all out, if the pimples on the face are few and distinct, the danger may be regarded as over, and no further treatment is required. If, however, the disease assume a confluent form, wakefulness and restlessness are apt to come on about the eighth day, and opiates in free doses may be prescribed with benefit. If the pustules are abnormally torpid in reaching their maturity, it may be expedient to administer strong broths, or even wine; and when the pustules are livid, and intermixed with Petechiæ (q. v.), bark and acids must be additionally ordered, although the patient is then too often beyond the reach of help. During the secondary fever, the bowels must be kept gently open, and opiates should be prescribed once or twice each day. A more nourishing diet is now called for, and wine should be given if the pulse is very weak. The external itching is partly relieved by the opiates, but local applications are also employed; cold cream, or a mixture of equal parts of olive oil and lime-water, may be thus used with advantage. Special methods have been devised for the purpose of preventing the pitting or seaming of the face, which is often a hideous permanent disfigurement to the patient. The best application of this kind is probably that of nitrate of silver. Mr Higginbottom, who first suggested this application, touches each distinct papula with a solid stick of lunar caustic, previously moistened; but when the spots are confluent, he washes the whole face, about the third day after the eruption, with a strong solution of this salt, containing eight scruples to the ounce of water. In the Paris hospitals, various mercurial preparations are employed, which are said to cause the pustules to abort. M. Briquet recommends mercurial ointment simply thickened with powdered starch. Dr Wood of Philadelphia remarks, that as the ointment sometimes salivates, it should be diluted with an equal quantity of lard before the starch is added. Professor Bennett of Edinburgh recommends the application of calamine (carbonate of zinc) mixed with olive oil; it forms a coherent crust, and thus excludes the air.

During the period of desquamation, an occasional warm bath may be prescribed with advantage; and the patient should always resort to this measure, as a precaution against carrying the contagion about with him, before again mixing in society.

The history of this remarkable disease is clothed in considerable obscurity. There is no evidence that it was known to the Greek or Arabian writers of the 6th c., and the first accurate description of it is that of Rhazes, an Arabian physician, who flourished early in the 10th century. It appears to have reached England towards the close of the 9th century. After the Crusades, it prevailed in most of the temperate countries of Europe, but did not reach the northern countries of Norway, Lapland, &c. for some time later. In 1517, it was carried from Europe to St Domingo; and three years later, it reached Mexico, where it committed fearful devastations, and whence it spread with intense virulence throughout the New World. (According to Robertson, three millions and a half of people were destroyed in Mexico alone.) In 1707, it was introduced into Iceland, when more than a fourth part of the whole population fell victims to it; and it reached Greenland still later (in 1733), when it spread so fatally as almost to depopulate the country. These cases are striking illustrations of the law that seems universally true, that a contagious disease is always most virulent on its first introduction to a new scene of action.

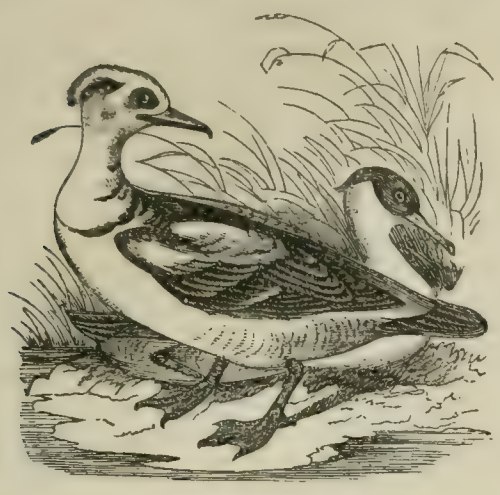
SMALLPOX IN SHEEP (*Variola ovina*). although resembling the smallpox of men, is a distinct disease, not communicable either by contagion or inoculation to men or children, or even to dogs or goats. Although common on the continent of Europe, it was unknown in Great Britain for at least a century, until in 1847 it appeared in Norfolk

and the eastern counties, and in the summer of 1862 in Wiltshire, near Devizes. Variolous sheep or infected skins appear in both cases to have imported the disease from abroad. About ten days after exposure to contagion, the infected sheep become feverish, have a muco-purulent nasal discharge, and a hot tender skin. The red pimples which first appear, in about three days become white, and afterwards leave scabs or ulcers. The weakness is great, and the mortality varies from 25 to 90 per cent. Good food and nursing are the appropriate remedies. Promptly and carefully must the sick be separated from the sound; but if the spread of the disorder be not thus immediately checked, the whole of the sound flock should be inoculated. The disease thus artificially produced appears in ten days, runs a mild course, occasions a loss of from two to five per cent., and in three weeks the disorder is got rid of, and all risk of contagion over.—Further details will be found in Professor Simmonds' 'Report on Smallpox,' in vol. 25 of the *Journal of the Royal Agricultural Society of England.*

SMALT, a name applied to the coloured glass compositions used for making the tesseræ employed in forming mosaics. See also COBALT.

SMART-MONEY. See RECRUITING.

SMEATON, JOHN, an eminent civil engineer, was born at Austhorpe, near Leeds, in 1724, and early shewed a bent towards mechanical pursuits. At the age of 15, he had constructed a machine for rose-engine turning. About 1750, he removed to London, to commence business as a mathematical instrument maker; but we find him in the following year resuming his desultory experiments in mechanical invention, an 'odometer' for ships, a compass, and improvements in water and wind mill-machinery being the chief products of his inventive genius. His improvements on mill-work were found on trial to be of great value, increasing the effective force by one-third, and gained S. the Copley Medal of the Royal Society in 1759. In 1753, he was chosen a member of the Royal Society; and in the following year, to extend his practical acquaintance with engineering, he visited the Netherlands, and inspected the embankments, canals, and other remarkable works of that country. In 1755, an event occurred which was to afford him the opportunity of attaining the very summit of his profession—the second wooden light-house on Eddystone rock was destroyed by fire in December. The speedy re-erection of another beacon was of the utmost importance, and the execution of the work was intrusted to Smeaton. The new light-house was built of stone; the cutting of the rock for the foundations commenced in August 1756, the building was executed between June 1757 and October 1759, and the lantern lighted on 16th October of the latter year. This great work, the greatest of its kind hitherto undertaken, remains to this day a stable monument of S.'s engineering skill. Yet he seems to have had little employment for some time subsequently, as he applied for and obtained in 1764 the post of 'receiver of the Derwentwater estate,' the funds of which were applied for the behoof of Greenwich Hospital; and this situation he held till 1777, by which time he was in full professional employment. The chief of his other engineering works were, the construction of the greater portion of Ramsgate harbour (1774); the laying out of the line of the Forth and Clyde Canal, and the superintendence of the excavation of most of it; the rendering of the Calder (Yorkshire) navigable; the erection of Spurn light-house, and of several important bridges in Scotland, together with an immense amount of mill-machinery. He also greatly improved Newcomen's steam-engine, but the mighty achievements of Watt in the same field threw his labours completely into the shade. He is said to have prevented the fall of the old London Bridge for many years by sinking a great quantity of stones around one of the piers, which had become undermined by the strength of the Thames current. In 1783, his health began to decline, and he retired from active business, dying at Austhorpe of paralysis, 28th October 1792. He was one of the chief promoters of the 'Society of Civil Engineers,' which was started in 1771, and after S.'s death published (1797) in three 4to volumes his numerous professional Reports, which were regarded by his successors 'as a mine of wealth for the sound principles which they unfold, and the able practice they exemplify.' For a large portion of his life S. was in constant attendance on parliament, which, in difficult or important engineering schemes, invariably demanded, and almost always followed, his advice—a proof not only of his eminence in his profession, but of his caution, judgment, and integrity. See the biography prefixed to his 'Reports.'



SMELL. See NOSE.

SMELT (*Osmerus*), a genus of the Salmon or Trout family (*Salmonidæ*), of which only a few species are known, differing from the salmon, trout, &c. in having long conical teeth on the jaws and tongue, and on the tip of the vomer, the rest of the vomer being destitute of teeth; two distinct rows of teeth on each palatine bone.—The COMMON S. (*O. eperlanus*), called *Spirling* or *Sparling* in Scotland, and *viridescens*) is a fish of 8 or 10 inches (rarely 12 inches) in length. The form is very trout-like—rather more slender—the tail larger in proportion, and more forked. The lower jaw is much longer than the upper. The scales are small; the back is whitish, tinged with green; the upper part of the sides shews bluish tints, the lower part of the sides and the belly are of a bright silvery colour. The S. has a peculiar, cucumber-like smell, and a delicious flavour, on account of which it is highly esteemed for the table, where it often appears as an accompaniment of other fish. The S. is partly an inhabitant of fresh water, and partly of the sea. It ascends rivers to no great distance from the sea in autumn, and descends in spring. Great numbers of smelt are taken in estuaries, and near the mouths of rivers, by small-meshed nets. They are also taken on the open sea-coasts, chiefly in New England. Two species of fresh-water smelt occur in the lakes of Maine, which are smaller than the marine S.; they are *O. spectrum* and *O. abbottii*, Cope. The common smelt is known as *Spirling* or *Sparling* in Scotland, and *Eperlan* in France, and though found both on the eastern and western coasts of Britain, the S. is unknown on the south coast of England, where the name S. or SAND S. is given to the Atherine (q. v.).—Another British species, the HEBRIDEAN (*O. Hebridicus*), discovered near Rothesay in 1837, is rare and unimportant.—The EUROPEAN S. (*O. eperlanus*) is regarded as distinct from the Common Smelt. It has a shorter body and a whiter back. The attempt has been successfully made to keep the S. continually in fresh-water ponds, in which it not only throve well, without loss of flavour, but propagated abundantly. No effort has yet been made to turn this discovery—not a very recent one—to any economical account.

SMELTING. See IRON.

SMEW (*Mergellus albellus*), a bird of the family *Anatidæ*, very nearly allied to the goosander and mergansers, but having a shorter bill. The whole length of the male is not quite 18 inches; that of

the female, not quite 15. The S. is only known in Britain as a winter visitant, appearing in greatest numbers in severe winters, and sometimes on

Smew (*Mergellus albellus*).

inland lakes and ponds, as well as on the sea-coast. It abounds on the northern coasts of Asia, and in some parts of continental Europe.

SMILA'CEÆ, a natural order of exogenous plants, ranked by Lindley in his class Dictyogens (q. v.), and consisting of herbaceous or half-shrubby plants, generally more or less climbing, with reticulated leaves, and bisexual or polygamous flowers, a 6-parted perianth, six stamens, a free 3-celled ovary, with cells one or many seeded, three stigmas, and a roundish berry. There are about 120 known species, mostly of the genus *Smilax*, scattered over the globe, but most numerous in the temperate and tropical parts of Asia and America. The root-stocks (*rhizomes*) of many species yield Sarsaparilla (q. v.). But some species have fleshy tubers, particularly *Smilax China*, a native of China and Japan, the tubers of which are very large and nutritious, and used for food. *Smilax pseudo-China*, an American species, has similar tubers.—The roots of *Roxburghia viridiflora*, after being boiled and soaked in lime-water, to remove their acridity, are preserved in syrup as an article of food in the Eastern Peninsula and Malayan Islands. The stems of this plant are sometimes 100 fathoms long.

SMITH, Adam, the founder of political economy as a separate branch of human knowledge, was born in the town of Kirkcaldy, in Fifeshire, on the 5th of June 1723. His family belonged to the respectable middle class of Scotch life; his father was comptroller of the customs at the port of Kirkcaldy, and his mother, Margaret Douglas, was the daughter of a small Fifeshire laird. His father died a short time before his birth, and he was the object of the care and solicitude of a widowed mother, to whom he was closely attached, and who long lived to be proud of his attainments. When he was no more than three years old, the poor woman got a sad fright, from a calamity hardly known at the present day—the child was stolen by gipsies; but he was tracked and recovered by his uncle as they were seeking a hiding-place in the neighbouring wood of Leslie. This was the only adventure in his quiet life. After getting the usual burgh-school education in Kirkcaldy, he was sent, in 1737, to the university of Glasgow. He there secured an exhibition on the Snell foundation, which took him to Balliol College, Oxford. He studied there for seven years, and left traditions as of a man of large acquirements and peculiar independence of thought. It is said that he was intended for the English Church, but if so, his own convictions crossed the designs of his friends. He returned to Kirkcaldy, and lived for a while with his mother there in undisturbed seclusion and study. It was said to be his practice to stand ruminating, with his back to the fire, and his head leaning against the chimney-piece—and over an old fireplace in Kirkcaldy it used to be shewn how he had thus worn a piece off the paint. In 1748 he came to Edinburgh, where silently and unostentatiously he became one of the brilliant little circle of men of letters who were then rising to importance. In 1751, he got the chair of Logic in the university of Glasgow, and this was changed a year afterwards for that of Moral Philosophy. In 1759, appeared his *Theory of Moral Sentiments*, celebrated for its reference of the mental emotions to the one source of sympathy. The *Dissertation on the Origin of Languages* was published along with the later editions of this book. Both had a great reputation in their day, and although they are now among obscure books in comparison with that other by which the author's name is remembered, the position they held with respectable thinkers gave a hearing to his doctrines on political economy which they would hardly have otherwise obtained. In 1762, the university of Glasgow gave him the degree of Doctor of Laws. In the following year he undertook a task, which might at first seem very uncongenial to a mind like his, given to retired study and independent thought and action. He became 'governor' or travelling tutor to the young Duke of Buccleuch. He was then sedulously collecting materials for his great work, and no doubt the inducement to accept of the office was the opportunity it gave him for travelling and seeing for himself. He had the opportunity of being nearly a year in Paris, and of mixing in the circle of renowned wits and philosophers of the reign of Louis XV. In 1766, his function came to an end, and he returned to Kirkcaldy to live in the old house with his mother. The year 1776 was an era in the history of the world as well as that of the Kirkcaldy recluse, in the appearance of the *Inquiry into the Nature and Causes of the Wealth of Nations*. If there was any living man to whose works he was indebted for the leading principles of this book, it was David Hume, and it was from him, as best understanding the fulness and completeness of the exposition, that it had its first emphatic welcome. He wrote immediately on receiving it: 'Euge Belle.—Dear Mr Smith—I am much pleased with your performance; and the perusal of it has taken me from a state of great anxiety. It was a work of so much expectation by yourself, by your friends, and by the public, that I trembled for its appearance, but am now much relieved. Not but that the reading of it necessarily requires so much attention, and the public is disposed to give so little, that I shall still doubt, for some time, of its being at first very popular. But it has depth, and solidity, and acuteness, and is so much illustrated by curious facts, that it must at last take the public attention.' This was not destined to be exactly the literary history of this great work. Its startling doctrines, fine clear style, and abundant illustration from curious facts took at first; but counteracting influences arose when people saw how far the new doctrines went in playing havoc with old prejudices. The French revolution set the mind of this country bigoted against everything that breathed of innovation. It was known that the younger Pitt participated at first in S.'s free-trade notions, but he had afterwards, whether from permanent connection or temporary policy, to put himself in the foremost ranks of the enemies of innovation. It was not until long after

the terrors of that epoch and the nervous vicissitudes of the war had passed over, that S.'s work had an opportunity to revolutionise the public mind on matters of trade and finance. It came up, as it were, the leader of a great literary host, for expounders had crowded in numbers round *The Wealth of Nations* as the text-book of sound economy. Of a book so well known and so much read, it is needless to speak. The only reproach brought against it is, that it is not systematic in its form, and that its nomenclature is not exact. But its author was not arranging the results of established knowledge—he was rather pulling down existing structures, compounded of ignorance and prejudice. Nor, indeed, have those who have attempted to make an exact science out of political economy, practically vindicated the reproach they have cast on him of being unmethodical. Whatever we may yet come to, very few portions indeed of political economy admit of being treated as exact science. It is too closely connected with human passions and energies, and consequently with special results and changes, to be so treated; and the best books on the subject are still characterised by the discursiveness and mixed philosophy and fact of the *Wealth of Nations*. In 1778, S. was made a Commissioner of Customs. The only effect of this was to bring him to Edinburgh, and increase his means for indulging in his favourite weakness, the collection of a fine library; for he was, as he called himself, a 'beau in his books.' In 1784, he suffered that affliction which was sure to come if he lived long enough for it—the loss of his worthy mother. He followed her six years afterwards, dying in July 1790.

SMITH, Alexander, poet, was born at Kilmarnock, in Ayrshire, December 31, 1830, received, as a boy, a fair English education, and passed from school into a Glasgow warehouse as a pattern designer. While following this occupation, he began to write poetry. His first volume, entitled the *Life Drama*, was published in 1853, and created something like a furor in literary circles. A reaction, however, followed, and the author had scarcely found himself famous when he began to be abused. The faults of his book were obvious enough: every page contained evidence of immaturity, and its natural result, extravagance; while a rather narrow reading having made him passionately attached to a few modern poets, as Keats and Tennyson, their peculiar turns of expression reappeared in his verse, and gave colour to the charge of plagiarism, which was pushed to an absurd length. But impartial critics were not slow to perceive a richness and originality of imagery that more than atoned for all defects of taste and knowledge. In 1854, S. was appointed Secretary to the university of Edinburgh; and in the following year, along with Sydney Dobell (q. v.), produced a volume of *Sonnets on the War*. Subsequently he wrote *City Poems* (1857), *Edwin of Deira* (1861), and several prose works, as *Dreamthorp* (1863), *A Summer in Skye* (1865), *Alfred Hagart's Household* (1865), and *Last Leaves, Sketches, and Criticisms*, edited, with a memoir, by P. P. Alexander (1868).—The style of his contributions to the magazines is distinguished by picturesqueness, polish, and originality. He died in 1867.

SMITH, James and Horace, authors of *The Rejected Addresses*, were sons of an eminent London solicitor. James was born February 10, 1775, died December 24, 1839; Horace was born December 31, 1779, died July 12, 1849. James followed his father's profession, and succeeded him as solicitor to the Board of Ordnance; Horace adopted the profession of a stock-broker, and realised a handsome fortune, on which he retired with his family to Brighton. Both were popular and accomplished men—James remarkable for his conversational powers and gaiety, and Horace (the wealthier of the two) distinguished for true liberality and benevolence. The work by which they are best known is a small volume of poetical parodies or imitations, perhaps the best in the language. On the opening of the new Drury Lane Theatre in October 1812, the Committee of Management advertised for an address to be spoken on the occasion, and the brothers Smith adopted a suggestion made to them, that they should write a series of supposed 'Rejected Addresses.' They accomplished their task in the course of a few weeks—James furnishing imitations of Wordsworth, Southey, Coleridge, Crabbe, Cobbett, &c.; while Horace contributed imitations of Scott, Byron (all but the first stanza), Monk Lewis, Moore, and others. In point of talent, the authors were about equally matched; for though James had the greater number of successful imitations, the one by Horace of Scott, is the most felicitous of the whole. It is a curious fact in literary history that a work so exceedingly popular should have had great difficulty in finding a publisher; and that the copyright, which had been originally offered to Murray for £20, and refused, was purchased by him in 1819, after the book had run through 16 editions, for £131. The authors received above £1000 from the sale of the work. James was afterwards an occasional contributor to the periodical literature of the day, and author of the humorous theatrical entertainments of Charles Mathews (for which he received £1000). Horace S. wrote several novels—*Brambletye House*, *Tor Hill*, &c.

SMITH, Joseph. See Mormonism.

SMITH, Rev. Sydney, a celebrated wit and humorist, and the original projector of the *Edinburgh Review*, was born at Woodford, in Essex, in 1771. His father was an eccentric English gentleman of moderate independence; his mother was the grand-daughter of a French refugee; and Sydney, it was said, fairly represented both nations. He was educated at Winchester School and New College, Oxford, and having entered the church, became curate of Amesbury in Wiltshire. 'The squire of the parish,' he says, 'took a fancy to me, and requested me to go with his son to reside at the university of Weimar; before we got there, Germany became the seat of war, and in stress of politics, we put into Edinburgh, where I remained five years.' During this time, he officiated in the Episcopal chapel there, and published *Six Sermons*, 1800. In conjunction with a few accomplished literary associates—Jeffrey, Horner, Brougham, Dr Thomas Brown, Playfair, &c.—S. started the *Edinburgh Review*, the first number of which appeared in October 1802, constituting a new era in the history of periodical literature, and of independent thought and criticism in this country. In 1803, S. removed to London, and was soon popular as a preacher, as a lecturer on moral philosophy (1804–1806), and as a brilliant conversationist, the delight and wonder of society. Church preferment, however, came slowly. In 1806, during the short reign of the Whigs, he obtained from Lord Erskine, when Lord Chancellor, the rectory of Foston-le-Clay, in Yorkshire; some 18 years afterwards, the Duke of Devonshire gave him the living of Londesborough, worth £700 per annum, to hold until Mr Howard, son of the Earl of Carlisle, came of age. In 1828, Lord Chancellor Lyndhurst presented him to a prebendal stall in Bristol, and enabled him to exchange Foston for Combe Florey, a more desirable rectory in Somersetshire. In 1831, Earl Grey appointed him one of the Canons Residentiary of St Paul's;

and this completed his round of ecclesiastical preferments. He sighed for a mitre, but it never came; and Lord Melbourne is said to have regretted this omission in his career as Prime Minister. The writings of S. subsequent to 1800 were his contributions to the *Edinburgh Review*, which he collected and republished, with other miscellaneous works, in 1839; *Peter Plymley's Letters*, written in 1807, to promote the cause of Catholic emancipation, and abounding in wit and irony worthy of Swift; *Sermons* in two volumes, 1809; *Speeches on the Catholic Claims and Reform Bill*, 1825—1831; *Three Letters to Archdeacon Singleton on the Ecclesiastical Commission*, 1837—1839; *The Ballot*, a political pamphlet, 1837; *Letter to Lord John Russell on the Church Bills*, 1838; *Letters on Railways*, 1842; *Letters on American Debts*, 1843; &c. Though gay, exuberant, and witty to the last, S. suffered from periodical attacks of gout and other complaints, and he died on the 22d of February 1845. Ten years afterwards, his daughter, wife of Sir Henry Holland, physician, published a Memoir of her father, with a selection from his letters.

The works of S. were mostly written on temporary topics and controversies, yet they bid fair to take a permanent place in our literature as specimens of clear and vigorous reasoning, rich unctuous humour, and solid good sense. His jokes, exaggeration, and ridicule are all logical, driving home his argument; and his wit was sportive, untinctured with malice. His views on political and social questions were moderate, wise, and practical; and he lived to see most of them realised. He erred at times in treating sacred subjects with levity and seeming irreverence; but this fault was one of natural temperament, and had no root in infidelity. He was a sincere, benevolent, and good man, a true patriot, and a happy Christian philosopher.

SMI'THFIELD. This name has become so celebrated, in connection with a cattle-market in London, that it has been applied to similar establishments elsewhere. S., in the 12th c., was an open spot which served the citizens as a playground and a place for a stroll. Being a little north of Newgate, and west of Aldersgate, it was outside the city walls. It was in S. that the rebel Wat Tyler met his death in 1381. Several noted tournaments were held here; and the place is associated with trials by battle, the burnings of martyrs, public executions during many centuries, and a variety of incidents connected with the history of the metropolis.

The most celebrated fair in England, Bartholomew Fair (q. v.), was always held in Smithfield.

A cattle-market was held in S. at least seven centuries ago, for Fitzstephen mentioned it in 1150. The corporation had official control over the market for more than 500 years, dating from 1345; and the city authorities have never to this day relaxed their hold over the one only live-cattle market in the metropolis. At one time, there was a project for removing the market to a field near Sadlers' Wells, at another, to a spot near the north end of Gray's Inn Lane; while a spirited projector spent £100,000 in building a new market at Islington; but powerful influences prevented the removal of the cattle-market until 1855. The last market-day in the old spot was on June 11th in that year; after which, the trade was transferred to the large and very complete establishment built by the corporation at Pentonville. Since that day, S. has been of very little practical use. Many conflicting propositions have been made for its appropriation during the last ten years; but it is only now (January 1866) that the plans are definitely arranged. Three railways, sunk deeply below the ground level, occupy parts of the area—one going eastward to Aldersgate and Finsbury, one southward to Ludgate and Blackfriars, and one north-westward to King's Cross and the north of London. In convenient proximity to these, will be a magnificent Dead-meat Market, from the designs of Mr Horace Jones, the city architect; it will be an architectural pile 620 feet long by 240 broad, traversed by numerous avenues, and having 200 shops for dealers in meat, mostly country-killed. This arrangement will enable the city authorities to abolish Newgate and Leadenhall markets, which have became serious obstructions to city traffic. At another part of S., will be a circular spiral road, to give descent to an underground goods-station. The remainder will be laid out in well-paved carriage and foot ways, with possibly a small ornamental green or enclosure opposite St Bartholomew's Hospital.

SMITHSO'NIAN INSTITUTION, at Washington, District of Columbia, U. S., was organised by act of Congress in 1846, in accordance with the will of James Smithson, who bequeathed the reversion of an estate amounting to $515,169 to the United States of America, to be devoted to 'the increase and diffusion of knowledge among men.' He was an Englishman, a natural son of Hugh, third Duke of Northumberland, and Mrs Elizabeth Macie, a niece of Charles, Duke of Somerset. He devoted his life to scientific pursuits, especially to chemistry, and died at Genoa in 1829. The Institution is governed by regents appointed by the Federal government, and has erected a spacious edifice, with museum, library, cabinets of natural history, and lecture-rooms, which occupies a prominent situation at Washington, the capital of the United States. It has long been a very valuable medium for exchanges with other countries, and its museum is enriched with the gatherings of national exploring expeditions. A portion of its funds is devoted to scientific researches, and the publication of works too expensive for private enterprise. It procures and distributes to students throughout the world collections illustrative of all natural sciences, and when investigated divides the collections with a long list of institutions. Under the management of Professor Joseph Henry, the secretary, have been organised departments of Astronomy, Ethnology, Meteorology, and Terrestrial Magnetism. Among the publications already issued are the *Smithsonian Contributions to Knowledge*, 16 vols. 4to, distributed gratis to libraries; *Annual Reports*, and *Miscellaneous Collections*. The courses of public lectures by eminent scientific men are among the attractions of the American capital.

SMOKE-NUISANCE, in London, is punishable with fine. The act applies to every furnace employed in working engines by steam, and every furnace in any mill, factory, printing-house, dye-house, distillery, bake-house, &c., which is not constructed so as to consume its own smoke, or which is so negligently used that the smoke is not consumed. The penalty is from two to five pounds. The statute only applies to the metropolis and to the river Thames.—In Scotland, a similar act is not confined to the Scotch metropolis.

Experience has already demonstrated that it is not impracticable, with skilful construction of furnaces, and careful management of fuel, to reduce the evil to such small proportions as to be scarcely worthy of notice; but, excepting in those towns where the law has been rigorously asserted, the nuisance continues to be a disgrace to the sanitary condition of our towns, and to our national character for cleanliness. The first conditions for smoke-consumption are—such an arrangement of the furnace as to insure a supply of atmospheric air sufficient for complete combustion, and a judicious

disposal of the fuel itself, in order that the vaporised carbon may be brought in contact with the air in a sufficiently hot condition. The first of these depends upon the construction of the furnace, the latter upon the care and skill of the fireman. The fireman who properly attends his fire keeps it pretty equally distributed as an even bed of burning coal over the fire-bars, and when a fresh supply of fuel is required, instead of throwing it in as far as possible over the burning surface, he piles it up near the furnace-door, as in fig. 1, which represents a common

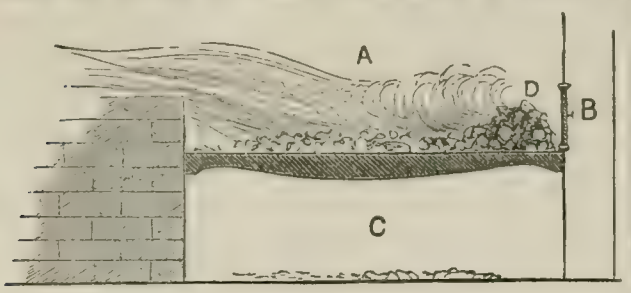


Fig. 1.

furnace, A the fire, B the door, and C the ashpit. The pile of coal, D, being acted upon by the heat, soon gives out its volatile products, and these passing over the intensely hot surface of the partially consumed fuel, are raised to the temperature necessary for combining with the oxygen of the air mixed with them. Thus with careful firing even an ordinary furnace will produce comparatively little smoke. This effect, however, may be heightened by special contrivances in the construction of the furnace. Mr Wye Williams of Liverpool, who has devoted a large portion of his life to this subject, and who has had very large opportunities of experimenting on a grand scale, has pointed out great improvements in the construction of furnaces, the chief principle of which is to bring the atmospheric air into contact with the fuel in a heated state, and to make the fire itself heat the air which is coming to supply it. This arrangement will be best understood by the drawing, fig. 2, which represents one of Mr Williams's

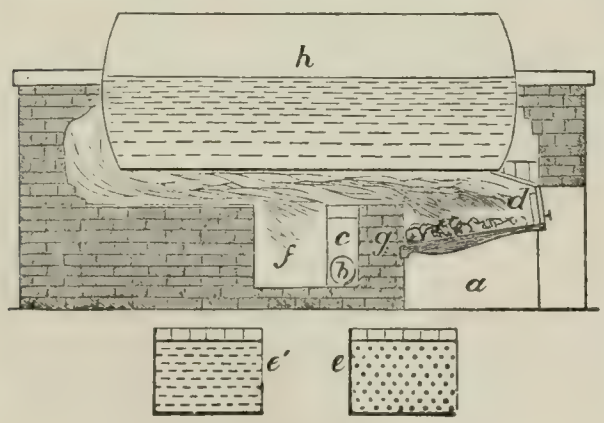

Fig. 2.

furnaces under a boiler, *h*. The fire is fed, as usual, through the door at *d*; it slopes downward to the bridge *g*, which rises much above the fire-bars, so that the flames have to pass over it. The bridge consists of two parts, the solid masonry or brickwork, *g*, and the chambered portion behind it, *c*, called the distributer. Into this a tube, *b*, opens through which a supply of atmospheric air enters, and becoming heated, passes through a number of plates with slits, or with perforations, as shewn in *ee'*, into the mixing-chamber, *f*; here the heated air enters into combustion with the carbon in the smoke-laden flame, deprives it of that element, and greatly increasing the heat by its combustion. Mr Williams, as managing director of the Dublin and Liverpool Steam-navigation Company, has had ample means of testing the value of the invention in his Company's works and vessels, and has realised the most successful results. His essay on the subject received the prize of the Society of Art, and its principles are very largely adopted.

Of plans depending upon the slow and regular admission of the fresh fuel by means of machinery, it will be sufficient to notice that of Jukes. His grate-bars are endless chains passing over rollers, and moved forward about an inch per minute. The coal employed is common siftings or screenings, which is heaped on the bars outside the furnace-door, which slides upwards. The door is left a little open, and by passing under it, the small coal is spread uniformly over the bars. The air is constantly supplied through the bars directly to the fuel while burning, and in this way perfect combustion is obtained. The bars, being slowly moved on, carry the ashes to the ashpit, which lies at the back of the grate. In 1848, Jukes's apparatus was applied to the furnace of the engine which prints the works of Messrs. Chambers, and has been completely successful; it is rare that a single particle of smoke can be seen issuing from the chimney, and the saving in coal and attendance is decided.

SMOKE-STACK, in a steam-vessel, is the group rising above the deck, and comprising the Funnels (q. v.), and the several escape-pipes for the steam, which are beside it. In ships-of-war, all these are frequently made telescopic, that they may be drawn down out of danger in action or in a strong head-wind.

SMOLE'NSK, a government of European Russia, bounded on the east by the governments of Moscow and Kaluga. Area 21,380 sq. miles. Pop. (1864) 1,137,212. S., which is watered by the Dnieper, Dvina, Gshat, Oka, Iput, &c., is one of the most fertile provinces of the empire, and produces great quantities of corn, hemp, and flax. Extensive forests yield splendid timber and mast. The rearing of swine is much followed. Manufacturing industry and export trade are both largely expanding.

SMOLENSK, a fortified town of Russia, capital of the government of the same name, is picturesquely situated on a range of steep declivities overlooking the river Dnieper, 250 miles west-south-west of Moscow. It is one of the oldest towns in the empire, having been a place of note in the 9th c., is surrounded by massive walls (with 21 towers), and has three cathedrals, 24 churches, and several monasteries, together with a diocesan seminary, a gymnasium, a military school for nobles, hospitals, &c. S. carries on manufactures of linens, soap, leather, and carpets, and a considerable export trade in corn and flax. Pop. 21,142. S. is historically notable as the scene of a bloody repulse of the Russians, under Barclay de Tolly and Prince Bagration, by Napoleon, August 17, 1812, when on his march for Moscow.

SMOLLETT, Tobias, an eminent British novelist, born in the year 1721, was descended from an old and distinguished family in Dumbartonshire. His grandfather, Sir James Smollett of Bonhill, was one of the commissaries or consistorial judges of Edinburgh, and sat in the Scots parliament as representative of his native county. Had the novelist survived about four more years than the term of his too short life, he would, as heir of entail, have succeeded to the ancestral estate in the beautiful vale of Leven. He lost his father while very young; but he was well educated, and afterwards apprenticed to a surgeon

in Glasgow. He is said to have wished to enter the army, and being disappointed, to have avenged himself on his grandfather, who thwarted his inclinations, by describing Sir James under the unamiable character of the old Judge in *Roderick Random*. This is related by Scott and all the biographers, but it must be wrong; for Sir James, the grandfather, died in 1731, when Tobias was only in his tenth year. The duty of attending to the education and settlement of the youth would naturally devolve on his widowed mother and on the Laird of Bonhill, his cousin. It is certain, however, that S. inherited no fortune; and in his 18th year, he went to London with a tragedy which he had written on the assassination of James I. of Scotland, and which he trusted would lead to distinction, if not wealth. He was grievously disappointed, and was glad to accept the post of surgeon's-mate on board one of the ships in the unfortunate expedition to Carthagena, in 1741. He soon quitted the service in disgust, although not before he had seen enough of naval life and character to be of inestimable value to him as a novelist; and returning to London, he commenced, and for the remainder of his life followed, the profession of an author. He made, indeed, repeated attempts to obtain practice as a physician, and in 1750, got a diploma of M.D. from Aberdeen; but his hasty irritable temper and independent spirit, joined to his natural propensity to satire, were fatal to his hopes. Even his literary career was a ceaseless warfare. In 1748, in his 27th year, he produced his *Roderick Random*, which was read with the utmost avidity, and seemed at once to place its author very near, if not in the actual rank of Fielding as a novelist. In 1751, appeared *Peregrine Pickle*, a more ambitious and not less successful work; and in 1753, *Ferdinand Count Fathom*, an inferior production, though containing scenes of striking adventure and eloquent description. S. next translated *Don Quixote* (1755), in which, it is admitted, he was surpassed by Motteux and Jarvis. He then undertook the editorship of a new Tory journal, *The Critical Review*, which was the most unfortunate of all his engagements, as it involved him in endless quarrels and personalities. For one article, an attack on Admiral Knowles, he suffered three months' imprisonment, and was fined £100. In 1758, he published his *History of England*, 4 vols. quarto—a history from the descent of Julius Cæsar to the treaty of Aix-la-Chapelle, in 1748, but which was begun and completed in 14 months, realising for its author a sum of £2000. Though superficial and inaccurate, this history has passages of fine animated writing and masterly delineation of character. We next find S. involved in political controversy with Wilkes and others, and defending Lord Bute's administration; but he wanted tact and temper for work of this description, and reaped no laurels as a politician. Another novel appeared in 1760—1761, *The Adventures of Sir Launcelot Greaves;* in 1766, two volumes of querulous *Travels in France and Italy;* in 1769, *The Adventures of an Atom*, a political satire unworthy of its author; and in 1771, only a few months before his death, *The Expedition of Humphry Clinker*, the best of all the novels of S.; and in the opinion of the late Mr Thackeray, one of the very best in the whole range of imaginative literature. Worn out with literary cares, private misfortunes, anxiety, and ill-health, the novelist retired to Italy, and died at Leghorn, October 21, 1771, in the 51st year of his age.

As a novelist, S. is distinguished by his broad humour and burlesque, the great variety of his incidents and characters, and the excellence of his easy, picturesque style of narrative. He is often careless, but rarely dull. He does not indulge in digressions, like Fielding, and though less of a literary artist than his great English rival, his works are read with more intense interest. He had, in fact, greater imagination and poetical sensibility. He added largely to our stock of original characters and humorists —Strap, Tom Bowling, Morgan the Welshman, Lismahago, and Matthew Bramble are still unsurpassed. Delicacy of taste was denied to both Fielding and S., and perhaps the latter is the more gross and sensual of the two. But the novelist lived in a coarse age, and possessed an exuberant fancy. There is a good deal to regret and to condemn; but to an author who has conferred so much true, healthy pleasure and enjoyment on countless generations of readers, forgiveness is easily extended, and is soon lost in admiration.

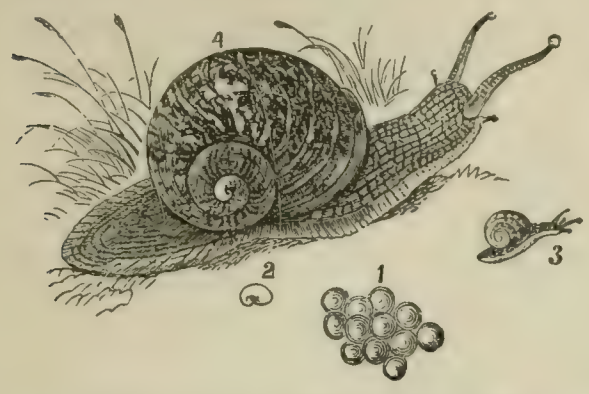
SMOLT. See SALMON.

SMORZA'TO, or SMORZANDO (Ital. dying away), a musical term, indicating a gradual diminution in tone, till the sound altogether fades away.

SMUGGLING is the offence of importing or exporting goods prohibited, or without paying the duties imposed on goods not prohibited. The offence in general leads to forfeiture of the goods. If goods are imported to defraud the revenue, treble value of the goods is forfeited. Many of the offences connected with smuggling are felonies, and punished with severity under the Customs' Consolidation Act. Where high protective tariffs separate the industry of adjoining countries, smugglers are certain to abound; no prohibitory decrees can keep the goods out. It was in vain that Napoleon fulminated the Berlin and Milan decrees for closing all continental ports against British shipping; British goods were landed at Salonica, passed on horseback through Hungary to Vienna, and thence distributed in all directions. Similarly, French manufactures reached England, often most circuitously: some a year in transit by way of Smyrna; others, *viâ* Archangel, after two years' journey. A vast cost was incurred in England in maintaining a Coast Guard and Preventive Service; but so long as smuggled goods could be sold at much lower prices than those at which they could be lawfully imported, so long would it be absolutely impossible wholly to suppress the traffic. The duties on French goods evaded in 1831, by the aid of smuggling, were estimated at £800,000. The true remedy for smuggling is a free, or, at least, very liberal tariff, without any prohibitive rates. Since the adoption of free trade by Great Britain, its Coast-guard has ceased to have any preventive duties to perform, and has been converted into the far better institution of a defence for the coasts from foreign foes, a reserve of trained men for the sea-service, and last, though far from least, a branch of skilful auxiliaries ready to aid any ship thrown in distress upon the British coast. The leading instances of smuggling still remaining are the execrable trade in slaves, and the great amount of contraband traffic from Gibraltar into Spain.

SMUT, the popular name of certain small fungi of the section *Coniomycetes*, and group or family *Uredineæ*, parasitical on plants, particularly on grasses, and notable for the great abundance of dark-coloured spores which they throw off. The name S., although somewhat variously used, is now very generally limited to the genus *Ustilago*, in which the character just mentioned, of the profusion of dark-coloured spores, is very remarkable. The name S. is often given to *Ustilago segetum*, or *Uredo segetum*, also called DUST-BRAND, a species very common and destructive, parasitic on wheat, barley, oats, and rye (see ERGOT), at the base of the germen and glumes, causing the death of the inner parts of

the flower, and then converting the whole into a sooty dusty mass. At first, a fine mycelium alone is seen, which ere long produces spores. There is no disagreeable smell, as in some of the allied fungi. A remarkable kind of S. infests maize, swelling the ears to an enormous size, sometimes even a foot in length. No remedy or preventive is known for smut. It does not seem to be communicated through infected grains; but perennial plants attacked by fungi of this kind remain diseased in subsequent years. Some kinds of S. attack other parts of plants than those chosen by *Ustilago segetum*. The reeds of the fenny districts of England are often much affected by a species (*Ustilago typhoides*), which much impairs their quality for all purposes, and has the more remarkable property of greatly affecting the health of the labourers employed in cutting and sorting them, producing not only a sense of oppression, but swelling of the head, the formation of vesicles, and inflammation of the bowels, besides other symptoms, such as are often produced by cantharides. Mr Berkeley says: 'The subject is worth attention, not only as curious in itself, but because it is very possible that, like the ergot, the fungus may afford a valuable addition to the Pharmacopœia.'

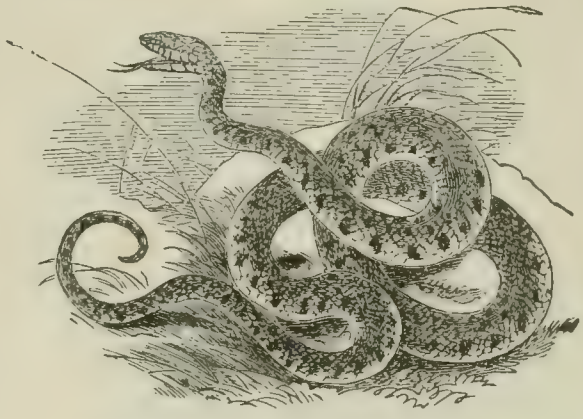


SMY'RNA, one of the most ancient and important cities of Asia Minor, and the only one of the Greek cities on the western coast which has retained its name and importance to the present day. The early history of S. is very obscure: varying accounts represent it either as originally an Ionian colony, or as having been at first an Æolian city, which, by an act of treachery, fell into the hands of Colophonian (Ionian) exiles, and subsequently, about 700 B.C., formed part of the great Ionian League. This earliest city of S., known among the Greeks as 'Old Smyrna,' was situated on the banks of the little river Meles, on the north-east side of the Hermæan Gulf, now the Gulf of Smyrna, and claimed the honour of being the birthplace of Homer; and here, near the source of the river, a grotto was shewn, in which he was said to have composed his poems. This old city of S. was destroyed, we are told, by the Lydian king Alyattes, and the place remained deserted and in ruins till after the Macedonian conquest, when the city was rebuilt at the distance of between two and three miles south of its original site. This city of 'New Smyrna' was founded by Antigonus, and enlarged and embellished by Lysimachus; it was laid out with great magnificence, and adorned with several fine buildings, among which was the *Homereum*, where the poet was worshipped as a hero. The city had an excellent harbour; and from its admirable situation, soon became one of the finest and most flourishing in the world. In the early history of Christianity, S. holds a distinguished place as one of the Seven Churches addressed in the Apocalypse, and as the scene of the labours and martyrdom of its first bishop, Polycarp. After various vicissitudes during the middle ages, it fell finally into the hands of the Turks, in whose possession it has since remained—the most flourishing city of the Levant.

The modern city of S. (Turkish *Izmîr*) occupies the site of New S., being built partly on the plain at the head of the gulf, partly on the declivity of a hill, the ancient Mons Pagus, and, from the sea, has an attractive appearance. There are some good quays, and some handsome buildings of stone; but the greater part consists of low wooden houses, for the most part of one story high; and the streets, with a few exceptions, are ill-paved, narrow, crooked, and dirty. The city, however, in these respects is better than most other Turkish towns, and improvements have of late years been made. The pop. is estimated at 160,000; of whom 90,000 are Turks, 40,000 Greeks, 15,000 Jews, 10,000 Armenians, and 5000 Franks. As is usual in Turkish towns, each people has its separate quarter. S. contains several Greek, Armenian, Roman Catholic, and Protestant churches, and about 20 mosques. There are six journals published here in five different languages. The harbour is excellent; ships of large burden anchor close to the quays; and the trade is most important and extensive. A railway, 83 miles long, constructed mainly with English capital and by English engineers, is in progress to Aidin, an important inland commercial town, and 48 miles of it were in operation in 1863. Another railway, extending 58 miles inland (to Cassaba) was begun in 1864, and will be finished, it is expected, early in 1866. The chief imports are woollen, cotton, and silk fabrics, iron, tin, lead, and hardware goods, coffee to the amount of 6,000,000 lbs. annually, sugar, spirits, spices, indigo, cochineal, &c. The exports consist of wool, cotton, silk, carpets, hides, opium, madder, copper, valonia, olive-oil, drugs, and gums, figs, raisins, and many other articles. In 1864, 2556 vessels (of which 900 were British), of 892,156 tons, entered and cleared the port; and the imports for that year amounted to £3,730,523—the exports to £4,832,979. S. is regularly visited by the ships of the French, Austrian, and Russian Steam-navigation Companies, and by traders from Great Britain and other countries. It suffered severely from fire in the summers of 1841 and 1845, and has been often ravaged by earthquakes and the plague. The city and its territory are governed by a pasha. Of the ancient cities, not much remains. Some slight ruins mark the site of Old Smyrna. Of New S., some remnants of the massive walls on the hill south-east of the city are still to be seen; the site of the Stadium in which Polycarp is supposed to have suffered martyrdom, is pointed out; there are some fragments of the ancient theatre, and columns belonging to a temple; and numberless architectural fragments have been built into the walls of the Turkish town, or used in the construction of graves in the large Turkish cemetery.

SMYRNA, GULF OF, an inlet of the Ægean Sea, on the west coast of Asiatic Turkey, is so called from the city of Smyrna (q. v.), which stands at its head. It is 40 miles long, is about 20 miles in greatest breadth, and contains several islands. Its waters are deep, and it affords good anchorage.

SNAIL (*Helix*), a genus of gasteropodous molluscs of the family *Helicidæ*, having generally a subglobose, sometimes a depressed, spiral shell; the mouth of the shell more or less encroached upon by the last whorl but one, strengthened with an internal thickened rib, its edges more or less reflexed; the *foot* of the animal long, and pointed behind; the tentacles four, the lower pair much smaller than the upper; the tongue armed with many—often from 100 to 200—longitudinal rows of teeth. The species are very numerous, more than 1400 having been described; besides fossil species, of which also there are many. Some of the groups have been constituted into separate genera by recent authors, but all retain the popular name S., which is indeed often extended to all the *Helicidæ*. As an instance of the general distribution of snails, it may be noticed that *Helix aspersa*, one of the common garden-snails of Britain, is found very generally throughout Europe, great part of Asia and the north of Africa.—Snails feed chiefly on vegetable substances, although they are very indiscriminate in their appetite, and even devour the dead of their own kind. The mischief which they



do to garden-crops is too well known; and gardeners lay down cabbage-leaves and the like to attract them, in order that they may be destroyed; any greasy substance increasing the attractiveness of the bait.—Snails delight in warm moist weather; in dry weather, their chief time of activity is during the night, and they hide themselves by day; but after rain, they come forth at any hour in

Common Snail and Eggs (*Helix aspersa*):
1, Eggs; 2, Appearance when newly hatched; 3, Slightly advanced stage; 4, Mature Snail.—Copied from Morton's *Cyclopædia of Agriculture*.

quest of food. At the approach of winter, or in very dry weather, they close the mouth of the shell with a membrane (*epiphragm*), formed by the drying of the mucous substance which they secrete, and become inactive and torpid. Some, as the Edible S. (*H. pomatia*), make a succession of such membranes; the outer one of which is also strengthened by a quantity of calcareous matter, the secretion being at first a white viscid fluid, but quickly hardening like plaster of Paris. When this is to be removed, a fresh secretion of fluid mucus softens it at the edges. Snails retreat into crevices for the winter, or into holes which they make in the earth, and which are roofed over with earth, dead leaves, &c., agglutinated by secreted mucus.—Snails are hermaphrodite, but mutual impregnation takes place, and when they are about to copulate, they excite each other by pricking or even piercing with a sharp calcareous glass-like style, affixed to a peculiar muscular sac which serves for its protrusion, and which is produced by recent secretion, not being found in them on dissection, except at the season of reproduction. Extraordinary as this circumstance is, it has been the subject of much exaggeration, and in works on natural history not of very old date, we read of snails throwing darts (*spicula amoris*) at each other, all which appears to be merely fabulous, although it is probable that the calcareous style may be often broken off in its use. The eggs of snails are round, and enveloped in a skin; they are generally deposited in little clusters. The eggs of the common garden-snails of Britain are about the size of peas, and are deposited just under the surface of the soil.—Snails possess in a very high degree the power of repairing injuries, not only of the shell—although the removal of the whole shell is fatal to them—but also of the soft parts. When the tentacles are cut off, they grow again; and even if the head is cut off, a new head is produced.—We do not think it necessary to describe any of the common British species, as there is nothing of peculiar interest connected with any of them; and the rarer and smaller species have still less claim to notice. The Edible S. (*H. pomatia*) of the south of Europe is the only one that deserves to be particularly mentioned. It is found in the chalk and oolite districts of the south of England, where it is said to have been introduced from the continent in the 17th c.; but this is very doubtful. It has a shell about two inches in diameter and two inches in height, whitish or pale tawny, with four darker bands, often not very distinct. It was much esteemed as an article of food by the ancient Romans, who fattened their snails in enclosures (*cochlearia*) made for the purpose, feeding them delicately on meal and boiled wine. It is still in much esteem for the table in various parts of Europe, and is occasionally used in England. Nor is it the only species so used; the common garden-snails are probably equally good, although not so large, and 'the glassmen at Newcastle once a year have a snail-feast; they generally collect the snails themselves in the fields and hedges the Sunday before the feast-day.'—Turton's *British Land and Fresh-water Shells*. Snails of different species are also an article of exportation on a small scale from England to the United States, packed in old casks, in which they are conveyed very well, fixing themselves one upon another to the cask, and leaving a vacant space in the centre. Snails boiled in milk are popularly regarded as a remedy for diseases of the chest, and for this purpose they are brought to Covent Garden market. If any benefit results from the use of them, it is probably due to their nutritious qualities.—Some of the tropical species of Helix are very large, and some have very beautiful shells.

SNAKE, a term synonymous with serpent.—The name Common S. is very generally given in England to a species very abundant in most parts of that country, and throughout Europe from the south of Scandinavia to the Mediterranean, although there is only one doubtful instance of its having been found in Scotland. Its range extends also over great part of the north of Asia. This species (*Natrix torquata* or *Tropidonotus natrix*) is also known as the

Ringed Snake (*Natrix torquata*).

Ringed S. and the Grass Snake. It belongs to the family *Colubridæ*, and to a section of it which some naturalists constitute into the family *Natricidæ*. It grows to the length of four and even five feet, although specimens exceeding three feet are rare. The female, as in serpents generally, is much larger than the male. The head is ovate, the muzzle rather narrow, the back part considerably broader than the neck; the body thickens towards the middle, and again tapers towards the tail, which is about one-fifth of the entire length, tapering to a rather sharp point; the gape is wide; the upper part of the head covered with large plates; the scales of the back have an elevated keel; those of the sides are larger, the keel merely rudimentary; the belly is covered with broad oblong plates; the under part of the tail has plates arranged in two rows. The teeth are very small, directed backwards, and arranged in two rows on each side of the jaws. The upper parts are grayish brown, tinged with green

at the back of the head are two crescent-shaped bright yellow spots, forming a kind of ring or collar; immediately behind these are two broad black spots, sometimes confluent. Two rows of small black spots are arranged alternately down the back, and larger ones at the sides; but these vary much in size and other particulars. The belly is pale lead colour, often marbled with black. The outer skin is changed at intervals varying according to the weather and other circumstances. Mr Bell says: 'I have known the skin shed four or five times during the year. It is always thrown off by reversing it; so that the transparent covering of the eyes, and that of the scales also, are always found concave in the exuviæ. Previously to this curious circumstance taking place, the whole cuticle becomes somewhat opaque, the eyes are dim, and the animal is evidently blind. It also becomes more or less inactive, until at length, when the skin is ready to be removed, being everywhere detached, and the new skin perfectly hard underneath, the animal bursts it at the neck, and creeping through some dense herbage, or low brushwood, leaves it attached, and comes forth in far brighter and clearer colours than before.' This snake is partial to damp situations, and often enters water, in which it swims with great ease, moving with singular gracefulness. It sometimes remains at the bottom for a considerable time. It sometimes climbs trees, its body, when ascending the stem, being 'straight and rigid as a stick.' See SERPENTS. It is very voracious; its food consists of frogs, small birds and quadrupeds, &c. Its teeth being incapable of tearing, cutting, or masticating food, the prey is always swallowed entire and living. Mr Bell heard a frog emit a cry some minutes after it had been swallowed by a snake. The S. has no poison-fangs. It has another kind of defensive armour, in certain glands, which emit a volatile substance of most offensive and penetrating odour, which, like that of the skunk, can hardly be removed from the skin or clothes. No such odour is emitted except in moments of irritation or other passion. The Common S. is oviparous: its eggs—usually about fifteen or twenty in number, whitish, with a parchment-like skin, and united into a string by a glutinous substance—are deposited in moist and warm situations, often in dunghills. The mother is said sometimes to coil herself around them, but generally leaves them unregarded. This snake is capable of being tamed, and becomes familiar with those who are kind to it, whilst the approach of a stranger, or of a dog or cat, alarms it, and causes an emission of stench. In winter, it seeks some refuge from severe cold, and becomes lethargic or dormant. Large numbers of snakes often take refuge in one hole; but seldom so many as in an instance recorded by Dr Carpenter, in which about 1300 were found in an old lime-kiln.

Much interest was excited in 1862 by the discovery in England of a species of snake, *Coronella lævis* (see CORONELLA and SERPENTS), previously unobserved in Britain, but common in the middle and south of Europe, and sometimes distinguished by the name of AUSTRIAN S., sometimes by that of SMOOTH S., none of the scales being ridged or keeled, as in the Common Snake. It inhabits much drier situations than those affected by the Common S., where it is often found in company with the Sand Lizard, situations more resembling those in which the viper is found. This snake is also more similar to the viper in form and appearance than the Common S., and these circumstances have probably led to its being often mistaken for the viper, and its existence in England remaining unnoticed so long. It attains a length of about two feet; is of a shining brown colour, ornamented with checkered irregular patches of black; a yellow mark on the back and sides of the head; the lower parts yellowish, with square black spots. The head is not flattened, as in the viper, but is narrowed in a similar way towards the neck; there is much difference in the plates of the head; the yellow mark on the head is a very characteristic distinction, and the back does not exhibit a broad zigzag pattern, as in the viper. Unlike the Common S., the *Coronella lævis* is ovoviviparous, the eggs being hatched within the mother. For an illustration of the *Coronella lævis*, see SERPENTS.

SNAKE-BIRD. See DARTER.

SNAKE-EEL, the popular name of the fishes forming the family *Ophisuridæ* of some naturalists, included by others, with all the eels, in the family *Murænidæ*, and distinguished by the want of a tail-fin, and the tail ending in a conical point like that of a serpent. They are inhabitants of the seas of warm climates. One species, *Ophisurus serpens*, is found in the Mediterranean. It attains the length of about six feet, and the thickness of a man's arm; is brown above, silvery beneath, and has a slender and pointed snout.

SNAKE RIVER, also called LEWIS' FORK, is the great southern branch of the Columbia (q. v.).

SNAKE-ROOT. See POLYGALA and ARISTOLOCHIA.

SNAKE-STONES, small rounded pieces of stone or other hard substance, popularly believed to be efficacious in curing snake-bites. A belief in their efficacy has been long and very widely diffused, and probably extended to Britain and other western parts of the world from the East. Small perforated balls and rings of various kinds of stone, ivory, &c., strung together like beads, were formerly used as snake-stones in Scotland, being given to cattle to chew when they were bitten by vipers. Of course they could only be expected to act as a kind of charm. Many of the snake-stones used in India and the further east seem to be of no greater value. Some of them, however, appear to be really efficacious, being applied to the wound and absorbing blood from it with the poison before it has entered the system. Remarkable instances are related of speedy cures thus effected. The snake-stone adheres for a short time to the wound, and then falls off. The wounded limb is meanwhile rubbed downwards. Two small snake-stones, each the size of a large pea, brought from India, and which were known to have cured a man bitten by a cobra, were found by Mr Quekett to be composed of some vegetable matter. Another, also known to have cured a cobra's bite, having been brought from Ceylon by Sir James E. Tennent, was examined by Mr Faraday, and was deemed by him to be 'a piece of charred bone, which has been filled with blood, perhaps several times, and then carefully charred again.'—See Buckland's *Curiosities of Natural History*, and Tennent's *Ceylon*, vol. i.

SNAKE-WEED, another name of BISTORT (q. v.).

SNAKE-WOOD, another name of LETTER-WOOD (q. v.).

SNAPDRAGON (*Antirrhinum*), a genus of plants of the natural order *Scrophulariaceæ*, consisting of annual and perennial herbaceous plants, chiefly natives of the temperate parts of the northern hemisphere. They have the calyx 5-parted: the corolla swollen at the base, but without a spur, and *personate* (Lat. *persona*, a mask), i. e., its mouth closed by the pressure of the lower against the upper lip; and the fruit is a 2-celled oblique capsule, opening by three pores at the apex. The

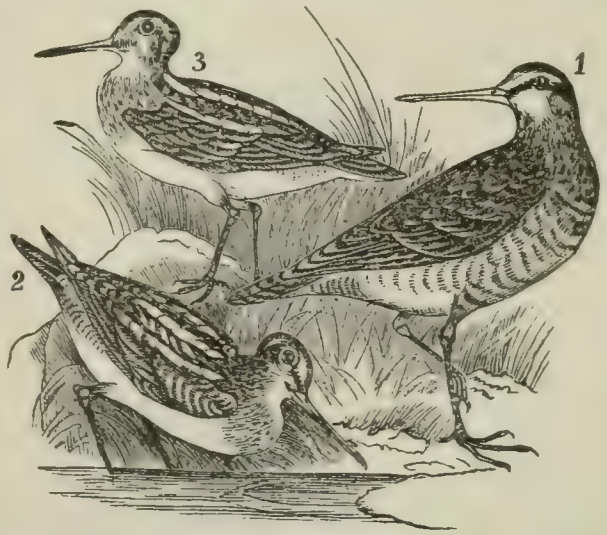
English name refers to a peculiarity of the corolla, the lower lip of which, if forcibly parted from the upper, so as to open the mouth, shuts with an elastic

Snapdragon (*Antirrhinum majus*).

spring or snap. Some of the species have very pretty flowers. *A. majus* has long been a favourite in our gardens, in which there are many fine varieties of it.

SNAPHAUNCE, an old musket of the 17th and first half of the 18th c., called also Asnaphan. See Lock.

SNEF'HÄTTEN. See Norway.



SNEEK, a prosperous trading and manufacturing town in the Netherlands, province of Friesland, 13 miles south-south-west of Leeuwarden. It is built in the form of an irregular triangle, has three canals, and good water-way to the sea. Rich meadow-lands, in some places tending to be marshy, surround the town, and in the neighbourhood is a considerable lake called the Sneekermeer. Pop. 9395, of whom about one-sixth are Roman Catholics, the remainder, except about 150 Jews, Protestants. S. is the largest butter and cheese market in the province; in 1863, the quantity sold reaching 4,887,025 lbs. of butter, and 2,001,828 lbs. of cheese. The principal buildings are the Reformed Church, Town-house, Baptist Church, and Jewish synagogue.

SNEEZE-WOOD (*Ptæroxylon utile*), a tree of the natural order *Sapindaceæ*, a native of South Africa, common in the eastern districts of Cape Colony. The timber rivals mahogany in beauty, takes a fine polish, is very solid, strong, and durable. It receives its English name, and its Dutch name, *Nieshout*, from the sternutatory properties of its sawdust, by which workmen are often much annoyed.

SNELL EXHIBITIONS. These exhibitions were founded in the year 1677 by John Snell of Uffeton, in the county of Warwick, for the purpose of educating Scottish students at the university of Oxford. Snell was born in the parish of Colmonell, in Ayrshire, in 1629, and entered the university of Glasgow in 1644. He afterwards removed to England, where, after holding several offices of a legal nature, he was appointed seal-bearer to the Court of Chancery. He died at Holywell, near Oxford, in 1679, leaving his estate of Uffeton, near Leamington, to trustees (the Vice-chancellor of the university of Oxford, the Provost of Queen's College, the Master of Baliol College, and the President of St John's College), for the foundation of the ten scholarships which now bear his name. The exhibitions have been the subject of much litigation in the court of Chancery, and are now administered under a scheme settled in 1861. The exhibitioners are nominated by the college of Glasgow, and receive about £108 annually each during five years. Candidates for these scholarships must have been born in Scotland, or must be sons of fathers born in Scotland, and must have resided for two years at least in Glasgow College, or for one year in that college, and two at least in some other college in Scotland. None are admitted to examination who have completed their 21st year, or have been members of the university of Oxford of more than two years' standing from the day of their matriculation inclusive. Two exhibitioners are nominated annually after public competition. The list of Snell exhibitioners includes not a few well-known names, such as J. G. Lockhart, Sir W. Hamilton, the late Bishop of London (Tait), &c.

SNIA'TYN, a town of Galicia, in Austrian Poland, is situated on the Pruth, and was formerly a frontier stronghold. It has tanneries, and a considerable trade in cattle and horses. Pop. 10,598, among whom are many members of the Armenian Church.

SNIPE (*Scolapax*), a genus of birds of the family *Scolapacidæ* (q. v.), having a very long straight bill, with nasal grooves extending almost to the tip, which expands a little, the upper mandible slightly exceeding the lower in length, the whole bill soft and very sensitive, smooth and shining in the living bird, but soon after death becoming pitted like the end of a thimble by drying. The head is compressed; the eyes large, and placed far back in the head, an evident adaptation to the mode of life, enabling the bird to guard against danger, whilst its bill is plunged in the mud. The feet have three toes before, divided to the base or very nearly so, not edged by membrane, the hind-toe short. The tail is short. The genus naturally divides itself into two sections, sometimes regarded as distinct genera, the first consisting of the Woodcocks (q. v.), to which the generic name *Scolapax* is appropriated; the second containing the species popularly known as Snipes, which receive the generic name *Gallinago*,

1, Solitary Snipe (*Gallinago major*); 2, Common Snipe (*Gallinago media*); 3, Jack Snipe (*Gallinago gallinula*).

and are distinguished by their lighter form, by their longer legs, and by having a little of the lower part of the tibia bare.—The Common S. (*S. gallinago*, or *Gallinago media*) is about 11 inches in entire length, the bill almost 3 inches. The sexes are alike in plumage, but the female is rather larger than the

male. The general colour of the upper parts is blackish brown, finely mixed with pale brown and with a rich buff colour; three pale brown streaks along the head; the neck and breast pale rust colour mottled with black; the belly white. The tail consists of 14 feathers. The S., when flushed, changes its course several times in a zigzag manner in the air, and then darts off very swiftly, so that young sportsmen find it a very difficult bird to shoot. The S. makes a very inartificial nest of a little dry herbage, in a depression of the ground, or sometimes in a tuft of grass or rushes. The eggs are four in number, pale yellowish or greenish white, the larger end spotted with brown. This species of S. is plentiful in all the moory and marshy parts of Britain, and generally throughout Europe, also in some parts of Asia, and it is found in the north of Africa. It breeds in Britain, even in the south of England, although many of the snipes which spend the winter in Britain migrate northwards in spring. The S. is capable of being tamed, and becomes very familiar, but is difficult to keep from the prodigious quantity of worms and other such food which it requires. A tame S. has been known to eat nearly twice its own weight of worms in 12 hours. The S. is in high esteem for the table, and is included amongst game in Britain.—The habits of all the other species of S. correspond very nearly with those of the Common Snipe. The GREAT S., or SOLITARY S. (*S.* or *G. major*), is comparatively a rare bird in Britain, but abounds in the extensive marshes of continental Europe, and is found also in Asia. Its entire length is about 12½ inches, the bill not quite so long in proportion as that of the Common Snipe. There are 16 feathers in the tail.—The JACK S., or JUDCOCK (*S.* or *G. gallinula*), the smallest of the British species, is like the Common S. in plumage. It is common in Britain, but mostly as a winter visitant, and is found also, during summer or winter, in most parts of Europe and of the north of Asia.—North America has a number of species. The COMMON AMERICAN S. (*S.* or *G. Wilsoni*) is about equal in size to the Common S. of Europe, and much resembles it also in plumage. The tail has 16 feathers. This species is abundant in summer in the northern parts of the United States and in Canada, in the more southern states in winter. It is in much request for the table, and is often caught in snares.—Snipes are found also in other parts of the world. The name S. is extended in popular usage to include the genus *Macrorhamphus*, in which the outer toes are connected at the base by a membrane. In other characters, as well as in plumage and habits, the similarity to the true snipes is very great. The RED-BREASTED S., or BROWN S. (*M. griseus*), of North America has been occasionally seen in Britain and in Scandinavia. In size it is nearly equal to the Common Snipe.

SNIPE-FISH. See TRUMPET-FISH.

SNI'ZORT, LOCH, a large and picturesque inlet of the sea, in the north-west of Skye (q. v.), between Trotternish Point and Vaternish Point. At its head, the loch is only a few furlongs broad; but it gradually expands, and at its entrance the breadth is over 7 miles. It is 13 miles long.

SNORRI STURLESSON, a learned historian, and a distinguished Icelandic politician, was born in 1178 at Hvamma, in Iceland, where his family, who traced their descent to the ancient kings of Norway and Sweden, had been settled since the early colonisation of the island. S. S. was placed at an early age under the care of Jon Loptson, the grandson of Sæmund Sigfusson, the learned compiler of the old Edda, by whom he was instructed in the history, mythology, and poetry of the North, as well as in classical literature. By his marriage, at the age of 26, with a rich heiress, and the speedy death of his father, S. S. early attained a position of wealth and influence, and by the free choice of the people, was elected supreme judge, or chief magistrate of the island. In this post, he was distinguished for his profound knowledge of the laws and civil institutions of his native country; but his ambition, avarice, and love of intrigue embroiled him personally in sanguinary feuds, and contributed to hasten the destruction of Icelandic independence. His love of intrigue led him to take part in the intestine troubles of Norway, and thus drew upon him the suspicion and ill-will of the Norwegian king, Hakon, who sent secret instructions to Iceland for his arrest; or, if need be, his assassination. The king's intentions were carried out to their fullest extent; and his numerous enemies joining together in a plot against him, S. S. was attacked in his own house, and murdered in the year 1241. S. S. was a poet of no mean order, and composed numerous *drapas*, or laudatory poems, on the kings and jarls at whose courts he sojourned. His great work is the *Heimskringla*, or Mythic Ring of the World, in which he records the history of the kings of Norway from the earliest times to the death of Magnus Erlingsson, in 1177; and which he compiled from ancient genealogical tables and other documents. It was translated into Danish about 1559 by Peder Clauson, and published first by Olaf Worm (Cop. 1633). This translation has been republished in more recent times by Gruntvig (3 vols., Cop. 1818–1822) and others. German, Swedish, and Latin versions have also been executed. S. S. is believed to have had a share in collecting and arranging the songs of the elder or poetic Edda (q. v.), and to have contributed very materially towards the compilation of the Skalda and other parts of the younger or prose Edda.

SNOW is the frozen moisture which falls from the atmosphere when the temperature is 32° or lower. It is composed of crystals, usually in the form of six-pointed stars, of which about 1000 different kinds have been already observed, and many of them figured, by Scoresby, Glaisher, and others. These numerous forms have been reduced to the following five principal varieties—1. Thin plates, the most numerous class, containing several hundred forms of the rarest and most exquisite beauty (figs. 1 to 6). 2. A spherical nucleus or

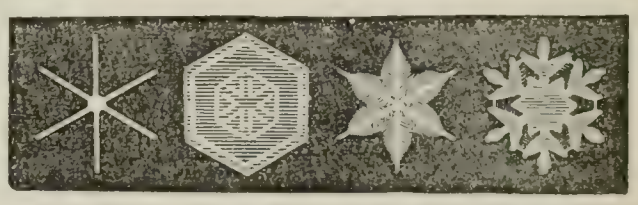


Fig. 1. Fig. 2. Fig. 3. Fig. 4.

plane figure studded with needle-shaped crystals (fig. 8). 3. Six or more rarely three sided prismatic crystals. 4. Pyramids of six sides (fig. 9). 5. Prismatic crystals, having at the ends and middle thin plates perpendicular to their length (fig. 7). The forms of the crystals in the same fall of snow are generally similar to each other. The crystals of hoar-frost being formed on leaves and other bodies disturbing the temperature, are often irregular and opaque; and it has been observed that each tree or shrub has its own peculiar crystals. Snow-flakes vary from an inch to $\frac{7}{100}$ths of an inch in diameter, the largest occurring when the temperature is near 32°, and the smallest at very low temperatures. As air has a

smaller capacity for retaining its vapour as the temperature sinks, it follows that the aqueous precipitation, snow or rain, is much less in polar

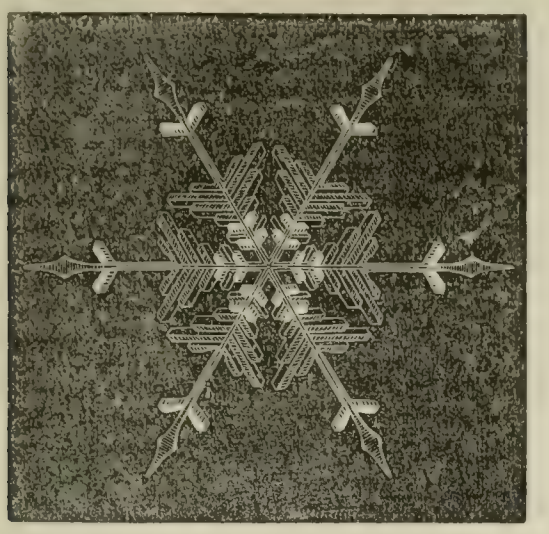

Fig. 5.

than in temperate regions. The white colour of snow is the result of the combination of the different prismatic rays issuing from the *minute* snow-crystals. Pounded glass and foam are analogous cases of the prismatic colours blending together

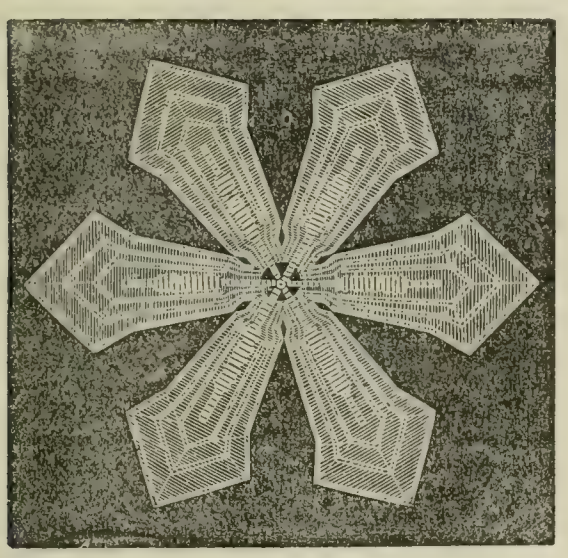

Fig. 6.

and forming the white light out of which they had been originally formed. It may be added that the air contained in the crystals intensifies the whiteness of the snow. See RED SNOW. The limit of the fall of snow coincides nearly with 30° N. lat.,

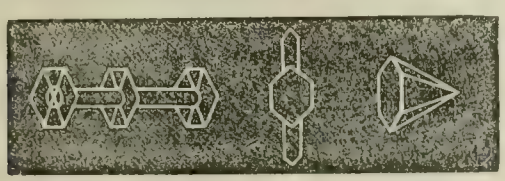

Fig. 7. Fig. 8. Fig. 9.

which includes nearly the whole of Europe; on traversing the Atlantic, it rises to 45°, but on nearing America descends to near Charleston; rises on the west of America to 47°, and again falls to 40° in the Pacific. It corresponds nearly with the winter isothermal of 52° Fah. Snow is unknown at Gibraltar; at Paris, it falls 12 days on an average annually, and at St Petersburg 170 days. It is from 10 to 12 times lighter than an equal bulk of water. From its loose texture, and its containing about 10 times its bulk of air, it is a very bad conductor of heat, and thus forms an admirable covering for the earth from the effects of radiation—it not unfrequently happening, in times of great cold, that the soil is 40° warmer than the surface of the overlying snow. The flooding of rivers from the melting of the snow on mountains in summer, carries fertility into regions which would otherwise remain barren wastes.

SNOW-BALL TREE. See GUELDER ROSE.

SNOWBERRY (*Symphoricarpus* or *Symphoria racemosa*), a bushy deciduous shrub of the natural order *Caprifoliaceæ*, a native of the northern parts of North America, and now very common in British shrubberies. It has simple leaves and small flowers; berries about the size of black currants, remaining on the bush after the leaves, quite white, but uneatable.—The name SNOWBERRY is also given to *Chiogenes hispidula*, a native of the bogs of North America.

SNOW BUNTING, or SNOWFLECK (*Plectrophanes nivalis*), a bird of the Bunting family (*Fringillidæ*), of a genus distinguished from the true buntings by the long and nearly straight claw of the hind-toe, in this resembling the larks. There is also an approach to larks in habits; there is a similar ease and celerity in running along the ground, and the song is very different from that of any of the true buntings. The S. B. abounds in summer in all parts of the arctic regions, and in winter in more southern countries of Europe, Asia, and America. Linnæus says it is the only living creature that has been seen 2000 feet above the limits of perpetual snow on the mountains of Lapland. Great flocks are seen in New York, particularly in severe winters. The Greenlanders kill great numbers, and dry them for winter use.

Snow Bunting (*Plectrophanes nivalis*).

SNOW BIRD (*Junco hyemalis*), one of the *Fringillidæ*, extremely abundant in the winter in the United States, but retiring to Canada in summer to breed. It breeds also on the summits of the Alleghanies to Georgia. It is slate-coloured, below the middle of the breast white, bill white. It has a weak, musical note. Other species of *Junco* occur in the Rocky Mountains.

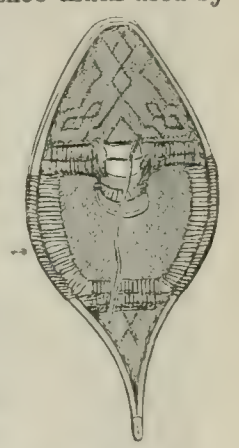
SNOW'DON, a mountain-range in Caernarvonshire, North Wales, stretches in a north-east-by-north direction from a point 5 miles north of Cricceith, near the head of Cardigan Bay, to near Conway; but is broken up by valleys and river-courses into four mountain groups, whose chief peaks are Carnedd-Llewelyn, 3460 feet; Moel-Siabod, 2878 feet; and *Moel-y-Wyddfa* ('the Conspicuous Peak'), the highest mountain in South Britain, 3571 feet above sea-level. Seen from the top, Moel-y-Wyddfa, the 'King of Snowdonia,' appears to send out three ridges, which gradually divide and subdivide, giving birth to numerous valleys and corries. The ascent of the highest peak of S. is effected by tourists from Llanberis (on the north), Beddgelert (on the south), Llyn-Cwellyn (on the

west), and Capel Curig (on the east); the first is shortest and easiest; the last is longest, most difficult, but at the same time by far the grandest. The district of 'Snowdonia' was made a royal forest by Edward I. of England, but was disafforested in 1649.

SNOWDROP (*Galanthus*), a genus of plants of the natural order *Amaryllideæ*, of the same tribe with Amaryllis, Snowflake, Crinum, &c. The three outer segments of the perianth spread, so as to make a bell-shaped flower; the three inner are shorter, erect, and notched at the summit. The flowers arise from a spathe. The root is bulbous, and produces two leaves and one single-flowered leafless stem (*scape*). The Common S. (*G. nivalis*),

Common Snowdrop (*Galanthus nivalis*).

a plant too well known to need description, is a native chiefly of the south of Europe, growing in woods and pastures. It is found apparently wild in some places both in England and Scotland, but is probably rather naturalised than native, having long been much cultivated in gardens. Another species of S. (*G. plicatus*), with much broader leaves, is found in the south of Russia and in Asiatic Turkey.



SNOW-LINE. The snow-line marks that height above the sea-level below which all the snow that falls annually melts during summer; higher than this lies the region of perpetual snow. No general rule for the height of this line can be given, owing to the different causes which may determine it. These are—the situation of the slope in respect of the sun's rays, and hence, other things being equal, it is higher on the south than on the north side of mountains; the situation with respect to the rain-bringing winds; the steepness of the slope; and the dryness or humidity of the region. The following are the observed heights of the snow-line in English feet, in different parts of the globe:

	N. Lat.	Height.
Spitzbergen,	78	0
Sulitelma, Lapland,	67	3,835
Kamtchatka,	59½	5 249
Unalaschta, W. America,	56½	3.510
Altai,	50	7,034
Alps,	46	8,885
Caucasus,	43	11.063
Pyrenees,	42¾	8.950
Rocky Mountains,	43	12,467
North Himalaya,	29	19,560
South Himalaya,	28	15.500
Mountains of Abyssinia,	13	14.065
Purace,	2¼	15,381

	S. Lat.	Height.
Nevados of Quito,	0	15.820
Arequipa, Bolivia,	16	17,717
Paachata, Bolivia,	18	20,079
Portillo, Chili,	33	1.473
Cordilleras Chili,	42½	6,010
Magellan Strait,	53½	3.707

From lat. 0° to 20°, it sinks only a very little; from 20° to 70°, it continues to fall equably; but from 70° to 78°, it sinks with great rapidity. To this general statement there are some important exceptions. It is about 4000 feet higher on the north than it is on the south side of the Himalaya, owing to the greater depth of snow that falls on the south side; to the greater dryness of the climate of Tibet, which increases the evaporation and the heating power of the sun's rays; and to the naked rocks and soil of the north absorbing more heat than surfaces covered with vegetation. It is higher in the centre of continents than near the coasts (the rain being less, and the heat greater), as seen on comparing the Pyrenees and Caucasus; and on the east than on the west coasts of continents, which is strikingly illustrated by Kamtchatka (5249) and Unalaschta (3510), situated respectively on the west and east coasts of the North Pacific. South of the equator, it rises from 0° to 18° very considerably, and more so on the west than on the east of the Cordilleras, owing to the small amount of rain and snow which falls on the west of these mountains. It is as high in 33° south lat. as in 19° north lat.; but south of this it sinks very rapidly, so that in the south of Chili it is 6000 feet lower than in the same latitude in the Rocky Mountains, and 3000 lower than in Western Europe. The mean temperature of the snow-line varies much from the equator to the pole—from 35° to 20° Fah. In the Alps, it is about 25°; and in Norway, about 23°.

SNOW-SHOES, a species of shoe much used by the Esquimaux, Laplanders, and others who inhabit those regions where snow prevails for a great portion of the year. It consists of a flat frame, of a lanceolate form (see fig.), from 8 to 14 inches in breadth at its widest part, and of great length—sometimes as much as 7, though generally about 4 feet. It is either wholly of wood, or is a wooden frame filled in with wicker-work or thongs, and has cross-straps on the upper surface to attach it to the foot. The broad surface prevents the foot from sinking in the snow.

Snow-shoe.

SNUFF. See Tobacco.

SNYDERS, or SNEYDERS, Francis, a Belgian artist, celebrated for his powers as an animal-painter, was born at Antwerp in 1579, and was formed in the school of Henry van Baelen. Originally, he confined himself exclusively to painting fruits, and worked with Rubens. In his pictures, with figures by Rubens, Jordaens, Honthorst, and Mierevelt, it is difficult to discover any difference of touch. For Philip III. of Spain he executed several hunting and battle pieces. S. knew how to give expression to the passions of the lower creation, and his bear, wolf, and boar fights are scarcely surpassable. The best specimens of the artist are contained in the galleries of Vienna, Munich, and Dresden, but there are also some fine pictures of his in private English collections. S. died at Antwerp in 1657.

SOAP (Lat. *sapo(n)*, Welsh *sebon*—the Romans considered soap to be a Celtic invention). This well-known material, according to Pliny, first became known to the Romans by their conquest of Gaul. There are some notices of it in the English version of the Bible, but it is believed that the words *borith* and *nether*, there rendered into soap, really mean potash and soda.

The *chemical composition* of soap may be explained as follows: The fixed fatty bodies, stearine, palmitine, and oleine (we do not include margarine, for it is now generally admitted that the fat to which this name was applied is merely a mixture of stearine and palmitine), when heated with alkaline solutions, undergo the remarkable change known under the title *Saponification*, or conversion into soap, during which process the fats yield up a clear viscid liquid, which, from its sweetness, is termed *Glycerine* (q. v.). The nature of this change may be ascertained by decomposing the soap that is thus formed, and which exists as a homogeneous transparent mass, freely soluble in warm water, by the addition of some acid, such as tartaric or hydrochloric, which combines with the alkali, and forms a soluble compound with it. A fatty matter separates in flakes, which melt on the application of heat, and form an oily layer on the surface of the fluid. This substance, when cold, is found to be very different from the original fat. It has acquired a strongly acid reaction, as may be ascertained by applying test-paper to it in its melted state, and it is freely soluble in alcohol, the solution being strongly acid. It at once forms a clear solution in hot alkaline liquids, while the original fat would under similar conditions have formed a milky-looking fluid. It is, in fact, a true *acid*, capable of forming salts, the potash and soda salts being known as *soft-soap* and *hard-soap*, which have been thus generated out of the elements of the neutral fat under the influence of the alkali. Stearine, when thus treated, yields *Stearic Acid* (q. v.); palmitine yields *Palmitic Acid* (q. v.); and oleine, *Oleic Acid* (q. v.); while common fat, which is a mixture of the three above-named fats, affords, on saponification with an alkali, and subsequent decomposition of the soap, a mixture of the three fatty acids. It is found that the weight of these acids and of the glycerine always exceeds by about 4 per cent. that of the fat originally employed. This may be explained by the fact, that each fat is a compound of a fatty acid with the base of glycerine, which has been displaced by the alkali in the act of saponification. The hydrated alkali, in displacing the glycerine base, gives up a portion of water to it, and thus increases its weight; while the fatty acid, on being separated from the soap, in like manner combines with a portion of water.

The term soap is sometimes extended in meaning, so as to include compounds of the fatty acids with other bases besides the alkalies, e. g., lime, baryta, magnesia, &c.; but these compounds being insoluble are inapplicable to the purpose of cleaning. The true soaps owe their cleaning power to their solubility, and their attraction for the matters that ordinarily constitute 'dirtiness.' The presence of a portion of tree alkali increases the detergent power, especially in the case of greasy matter.

Manufacture.—It is found in practice, that generally all such fats and oils as soon become rancid—that is, naturally decompose, and liberate their acids—are the most economical for soap-making. Besides the oils, fats, and alkalies, resin (q. v.) is used in order to economise the more expensive alkalies; a small portion of lime, dissolved by the water in the first stage of the process, also enters into the composition of soap. The chief oils or fats used in soap-making are tallow and grease, palm oil, cocoa-nut oil, and olive oil for hard-soaps; and linseed and hempseed oils for soft-soaps. The first stage in the manufacture of common soap is to produce a caustic alkaline *lye:* this is done in iron tanks, usually six feet in width, and four feet in depth, with a plug-hole at the bottom; sometimes they have a perforated false-bottom inside, which is converted into a filter by covering it with a piece of coarse canvas. In these tanks, alternate layers of soda-ash and quicklime are laid in regular proportions—the function of the lime being to deprive the carbonate of soda of its carbonic acid—and water is let in slowly, until the tanks are full. In this state they are left for nearly a whole day, when the plugs are withdrawn, and the liquid is received into a vessel placed below. The plugs are then replaced, and the tanks refilled with water, which, after remaining a sufficient time, is in the same way drawn off into another vessel. This is repeated as long as any alkali remains to be dissolved. Each drawing-off is kept by itself, and they are called *first-running*, *second-running*, and so on. The next step is to pump about 200 gallons of the weakest, which should contain not less than two per cent. of pure alkali, into the copper, which is an iron basin of large size; a ton of fat is added, and heat sufficient to boil gently is applied for about four hours. The fire being then allowed to go out, the lye is found to have lost its alkali, and in an hour or two settles down at the bottom of the copper, from which it is withdrawn, leaving the now partially saponified fat behind. To this is then added another portion of lye of the running next in strength to that used, and a fresh quantity of fat is also added; the boiling operation is repeated, and afterwards the spent lye is withdrawn. This process is repeated until all the lyes from the weakest to the strongest have been used. These successive operations usually occupy five or six days, by which time the whole quantity is completely converted into soap, a result which is known by various tests to the experienced workman.

But although the saponification has thus been effected, the material is not in a state fit for use; it has therefore to be reboiled with a quantity of water or very weak lye, until it is so diluted that its particles seem to be separating from each other; then the boiling is carried on with great vigour; and to prevent its boiling over, the men keep shovelling back the lye from the breast of the boiler, so as to break up the froth, and promote the evaporation of the water. After a time, the soapy particles distributed through the fluid begin to cohere until they are all united again in one pasty mass, resting on the top of the water; the cover is then put on the top of the copper, and the fire withdrawn, and the whole left standing for about three days, when the lid is lifted, and the soap is carefully removed from the top of the spent lye or water by means of ladles, which transfer it to wooden or iron tanks, made up of a number of frames of regular size, placed upon one another; each the thickness of a bar of soap. When the soap has *set*, a piece of wire is drawn successively between each two frames, and they are thus cut asunder with the soap they enclose. They are then set on their sides for a short time, and the soap becoming drier, is easily detached in the form of square cakes of uniform thickness. These cakes are then cut by wire transversely, so as to form the square *bars* of commerce.

To manufacture soap successfully requires much skill, for the materials are rarely of exactly the same qualities; the process cannot be reduced to the nice exactness of other chemical manipulations, therefore much depends upon the eye and the experience of those employed. If soaps become tinged with the iron of the boiler in which they are made, as they usually do, and contain too little water to render them sufficiently fluid to deposit these stained portions, the soap is then mottled, and these *mottled soaps* became favourites, because they were less mixed with water; but this distinction is

not now of much value, for they are successfully imitated. The Castile or olive-oil soaps of Spain are amongst the best. The palm-oil and resin soap, so largely manufactured in America, is the cheapest and best fitted for common use. Perfumed soaps are only used for the toilet, and are very various, according to the odour employed, and the artificial colours imparted to them. *Marine-soap* is made of cocoa-nut oil, soda, and water, and has the remarkable property of dissolving as well in salt water as in fresh, hence it is much used at sea for washing.

Soft-soap is comparatively little used, except for coarse purposes, in America; but in the northern parts of Europe, especially in Holland, it is chiefly used for washing linen, &c.

Several vegetables contain a principle called *saponin*, which is remarkably analogous to soap in its action, hence they are in different parts of the world used for washing clothing, &c. See SOAPWORT.

SOAP, MEDICAL USES OF. The only kind of soap that should be used internally is *White Soda Soap*. It is prepared from caustic soda, and either olive or almond oil. In its purest state, it is called *Medicinal Soap*, while in its less pure forms it is known as Alicant, Venice, or Spanish soap. When properly made, it should be perfectly soluble in pure water and in alcohol. It is chiefly employed to form pills of a gently aperient and antacid action. Pills containing a combination of soap and dried carbonate of soda, are of great use in certain forms of gravel. Soap is often added to pills as an adjuvant, or for the purpose of preventing them from becoming hard and insoluble. White soap affords a ready antidote in cases of poisoning with the strong mineral acids. *Soft-soap* ought to be made with olive oil and potash, and it should be of yellowish-white colour, inodorous, and of the consistence of thick honey. It is of great service, as an external application, either alone or in association with sulphuret of potash, and other remedies, in various cutaneous affections.

SOAPBERRY (*Sapindus saponaria*), a West Indian tree, of the natural order *Sapindaceæ*, the pulp of the fruit of which is used instead of soap in washing. This property belongs to other species of the same genus. With the exception of *S. marginatus*, found in the southern states of North America, the genus is entirely tropical. The use of the pulp as soap, if often repeated, is apt to injure linen; but it is capable of cleansing as much linen as sixty times its weight of soap. Each fruit contains a nut of a shining black colour. These nuts are very hard, and were formerly imported into Europe to be made into waistcoat buttons, being tipped with silver or other metal. They were little liable either to be injured by wearing or to be broken.

SOAP-STONE. See STEATITE.

SOAP-TEST. This test, for which science is indebted to Professor Clark of Aberdeen, is now universally employed for determining the degree of hardness of water. Every one knows how much more readily a lather is formed—as, for example, in washing the hands—with soft than with hard water. This is accounted for by the earthy bases of the hard water displacing the alkaline bases of the soap, and forming compounds insoluble in water. This is the foundation of the soap-test. A hard water of known strength is first prepared by dissolving 16 grains of pure carbonate of lime in pure hydrochloric acid, evaporating to dryness, and dissolving the resulting chloride of calcium in a gallon of distilled water. This gallon of chloride of calcium solution accurately represents a natural water whose hardness is due to 16 grains of carbonate of lime in a gallon. A solution of soap in proof-spirit is next prepared of such strength, as that a quantity of it which will fill 32 measures of a volumetric tube, each measure of which contains 10 grains, will be exactly able to convert 1000 grains' measure of the standard solution of hard water into the earthy soap described. This point is thus ascertained: The hard water is placed in a stoppered bottle, and the soap solution added to it by degrees, the bottle being shaken after each addition, when a bubble will form, which rapidly disappears so long as any lime is present; but when at last it is all used up, a froth of soap bubbles remains after hard shaking, such as to last unbroken for three minutes. If, now, a given sample of water be examined, and this point is reached at the expense of the entire 32 measures, it is a water of 16 degrees of hardness. Now, perfectly soft water consumes 2 measures of the soap solution before permanent bubbles are formed, so that a water of 16 degrees of hardness has in reality only consumed 30 measures of the soap solution. But $\frac{16}{30} = 0{\cdot}53$; hence, if any given measures of the soap-test be used in estimating the hardness of a water, we must first subtract 2 from the amount, and then multiply by 0·53; and the result will give us the degree of hardness. For example, let a given sample require 27 measures of the soap-test. On subtracting 2, and multiplying by 0·53, we find its hardness to be 12·25. Clark's Soap-test Table for Hardness of Water is given in the article 'Soap-test' in Knight's *English Cyclopædia;* and full details regarding the mode of working the test, to determine the amount of lime, magnesia, soda, sulphuric acid, and pure carbonic acid, are given in Dr Parkes's *Manual of Practical Hygiene* (Lond. 1864).

SOAPWORT (*Saponaria*), a genus of plants of the natural order *Caryophyllaceæ*, having a cylindrical or ventricose 5-toothed calyx, without any outer calyx or attendant bracteæ, five undivided petals with long claws, ten stamens, two stigmas, and a capsule opening at the top by four valves. Some of the species have very beautiful flowers. *S. Calabrica* has of late become one of the most favourite annuals of our flower-gardens.—COMMON S. (*S. officinalis*) is found on waysides, in thickets, and on the banks of streams, in most parts of Europe, although it is a somewhat doubtful native of Britain. Both the root and the leaves contain Saponin (q. v.), in consequence of which they are sometimes employed for washing. The brownish-red colour of the bark of the root, however, is apt

Soapwort (*Saponaria officinalis*).

to tinge white articles. The root of this plant has also medicinal properties, being aperient, resolvent, and alterative. It is sometimes sold as RED SOAP-ROOT.

Nearly allied to the genus *Saponaria*, but having an angular calyx and a 5-valved capsule, is the genus *Gypsophila*, some species of which are called SOAP-ROOT, and contain much saponin. Thus, the EGYPTIAN SOAP-ROOT (*G. struthium*), and the SPANISH SOAP-ROOT (*G. Hispanica*), called *Jabonera* in Spain, have been employed for washing from time immemorial, and the roots not having a dark rind, can be used for washing white articles, and are to some extent an article of commerce, being used for silken and other stuffs, the colours of which will not bear the application of soap. The roots of *Lychnis dioica*, one of the most common British plants, possess the same properties in an inferior degree.—The bark of *Quillaja saponaria*, a Chilian tree of the natural order *Rosaceæ*, contains much saponin, is generally used for washing in Chili and Peru, and there forms a considerable article of commerce.—Some of the tropical South Sea Islands produce a species of vine (*Vitis saponaria*), the stem of which, especially the thicker part, cut into pieces, and softened by cooking on hot stones, produces in water a rich lather almost equal to that of soap. See also SOLANUM.

SOBBING is merely a modification of the ordinary movements of respiration excited by mental emotions. It is the consequence of a series of short convulsive contractions of the diaphragm, and is usually accompanied by a closure of the glottis, temporarily preventing the entrance of air into the lungs.

SOBRAO'N, a village on the left bank of the Sutlej, 25 miles east-north-east of Ferozpur, near which, on 10th February 1846, a most obstinate battle was fought between the British army of 15,000 men, under Sir Hugh Gough, and a Sikh force numbering 30,000. The Sikhs were strongly intrenched, and vigorously resisted the attacks of their opponents, but the courage and perseverance of the latter ultimately gave them the mastery; the various earthworks were captured in succession, and the Sikhs driven across the Sutlej, with a loss in killed, wounded, and drowned of 13,000. Gough immediately followed up his victory by crossing into the Punjab in pursuit of the fleeing enemy.

SOCAGE, or SOCCAGE (originally *hlaford-socn*, seeking a lord; whence we have also *soc*, a right of holding a court), a tenure of lands in England, of which the characteristic feature is, that the service is fixed and determinate in quality, thereby differing both from knight-service and from villeinage. It was originally peculiar to the Anglo-Danish districts of England. At the time when the allodial tenure was converted into immediate dependence on the crown, this tenure seems to have arisen out of the necessity for commendation or seeking a lord. In Domesday, socmen are often mentioned as bound 'to seek a lord,' or free to go with their land where they pleased. The socmen of Stamford are said to be free to seek a lord, being only liable to the king for the toll attached to them as inhabitants of a borough. The obligation of socage in its origin has been compared to the mutual bonds of allegiance of later times so common in the Highlands of Scotland, and known as Bonds of Manrent (see MANRENT). Three kinds of socage have been enumerated as existing at a later period—viz., free and common socage, socage in ancient tenure, and socage in base tenure. The second and third kind are equivalent to tenure in ancient demesne and copyhold tenure (see DEMESNE ANCIENT, and COPYHOLD), and the first is what has generally and more properly been denominated socage, where the services were both certain and honourable. Besides fealty, which the socager was bound to do when required, he was obliged to give attendance at the court baron of his lord, if he held one, either for a manor or for a seigniory in gross.

By an act passed during the Commonwealth, and confirmed after the Restoration by 12 Car. II. c. 24, tenure by knight-service was abolished, and all lands except church-lands held in free alms, were directed to be held in free and common socage, which is now (with that exception) the universal tenure of real property in England and Ireland.

Socage tenures are unknown in Scotland, where, unless at a very early period, they never existed.

SOCIALISM, the name given to a class of opinions opposed to the present organisation of society, and which seeks to introduce a new distribution of property and labour in which organised *co-operation* rather than *competition* should be the dominating principle, under the conviction that the happiness of the race, and especially of the classes without capital, would be benefited thereby. Historically considered, Socialism, like many of the significant phenomena of our age, is a product of the French Revolution. That terrible outburst of popular discontent is most properly regarded as an anarchic attack on the social system that had its roots in the feudalism of the middle ages. The furious hatred of the court and the aristocracy, the passionate love of the 'people,' of 'humanity,' of 'liberty,' though called forth by special circumstances, and never formally worked out into a theory of social life, virtually contained in themselves the germs of all later proposed organisations. In the middle ages, the *right* of freely and fully enjoying life, property, and political independence was limited to a favoured few; while the great masses were condemned to dumb servitude, and a perpetual minority. Even the industrial population did not recognise the Socialistic idea. The members of the different guilds or fraternities claimed exclusive right to exercise certain branches of industry, and probably the great majority of the inhabitants of a town remained in a disregarded and dependent state. Amid such social conditions, resting, as they did, on a belief in the necessity of different distinct ranks, the free action of individual life, and even the vital progress of the whole community, became well-nigh impossible. We have not space here to trace the course of the various minor reforms that weakened the authority of the medieval theory of life; but we must not omit to notice the speculations of the political philosophers of the 18th c. in France, England, and Germany, as operating powerfully in favour of a new social system, in which the idea of humanity (assuming, at the French Revolution, as we have observed, the concrete form of the 'people') stands out prominently. Nevertheless, the first shape that the modern spirit of industry took, was not Socialistic, in the strict and proper sense of the term: it was rather individualistic, and found, as it still finds—for it is yet the prevailing theory—its natural expression in such proverbs as, 'A fair field, and no favour;' 'Every one for himself, and God for us all.' But still, even this lawless individualism is to be regarded as a protest against the false *class*-legislation of preceding times, and as an assertion of the absolute right of *each member of society* to a share in the general welfare. That it has not universally commended itself to civilised mankind, as a perfect system, is demonstrated by the appearance and temporary popularity of such schemes of society as those of Owen (q. v.), Fourier (q. v.), St Simon (q. v.), and the enthusiasm excited at

intervals in different parts of Europe by the promulgation of extreme communistic opinions. See COMMUNISM. It is objected to Socialism, under its various forms, that it makes human happiness too much dependent on material gratifications; that it robs man of that energy that springs from ambition; that it unphilosophically ignores an individualism and inequality to which Nature herself has given her inviolable sanction; and that, by the abolition of social rewards and punishments, it neither holds out any hope to the industrious, nor excites any apprehension among the indolent. On the other hand, we must admit that the vigorous assertion of Socialistic principles has led men to a more liberal and generous view of humanity as a whole. Moreover, it has forcibly called public attention to numerous evils that have sprung up along with the modern development of industry, for which no remedy—not even a name—had been provided; to the vital inter-dependence of all classes; and to the inadequacy of the individual or 'selfish' system, as it has been called, to redress the wrongs or cure the evils that inevitably spring from its own unchecked operation.

SOCIAL SCIENCE, a name that has of late years been given to the study of all that relates to the social improvement of the community. A society, called 'The National Association for the Promotion of Social Science,' was first organised at a meeting which was held at Lord Brougham's residence in Grafton Street, in July 1857, to consider the best means of uniting together all those interested in social improvement. Lord Brougham was appointed President; and at the request of the deputation from Birmingham, it was agreed that the first meeting should be held in that town. The annual meetings have been held each year at a different place. The Association was at first divided into five departments—Jurisprudence, Education, Punishment and Reformation, Public Health, and Social Economy—this last dealing with questions regarding capital, labour, and production; an additional department was added in 1860, under the title of Trade and International Law. The Association aims at promoting improvement in all matters falling within these departments, by means of bringing together, for free discussion, societies and individuals interested in the social problems which they involve. The amount of discussion has, at all the meetings, been very considerable, though there is some diversity of opinion as to whether the results have materially aided in solving the more difficult questions of the day.

SOCIETIES are associations of individuals for the promotion or accomplishment of some particular object. Such objects are numerous, including the promotion and investigation of almost every well recognised branch of science, art, and literature; the diffusion of knowledge, religion, and morality; intercourse between those of the same profession or trade; the removal of legal grievances; mutual aid in case of distress; and an abundance of other aims, which are either beneficial to the general public, or to the members of the society alone. In Great Britain, any number of persons may agree to constitute themselves a society, if the object of their union is legal. Those whose objects are scientific or literary are occasionally called *Academies* (q. v.), and under this or their own special names will be found notices of the chief societies at present existing. 'Secret' societies for the accomplishment of some object which involves a subversion of existing political arrangements, spring up from time to time in France, Ireland, Italy, &c.

SOCIETY ISLANDS, a small archipelago in the South Pacific Ocean, in lat. 16°—18° S., long. 148°—155° W., is formed of two clusters of islands, about 70 miles apart, and, in former times, politically distinct; both are now under French rule. Exclusive of islets, the group is formed of 13 islands—Tahiti or Otaheite, Maitia, Eimeo, Maiaoiti, Tetuaroa, Huaheine, Raiatea, Otaha, Borabora, Marua, Tuba, Lord Howe's Island, and Scilly Island. Area estimated at 450 sq. m. (*Almanach de Gotha*, 1865), pop. 13,847, according to the *Annuaire de Taiti*. All the islands closely resemble each other in appearance. They are mountainous in the interior, with tracts of low-lying and extraordinarily fertile land occupying the shores all round from the base of the mountains to the sea. They are surrounded by coral reefs, are abundantly watered by streams, and enjoy a temperate and agreeable climate. Almost every tropical vegetable and fruit known is grown here; but agriculture is in a backward state. The animals are those usually found in the South Sea Islands. The inhabitants belong to the Malay race, are affable, ingenious, and hospitable, but volatile and sensual. The practice of tattooing has almost wholly disappeared, and the native costume now closely resembles that of civilised nations. There are now no native manufactures, these having been entirely superseded by imported goods. Cocoa-nut oil, oranges, lime-juice, kauri shells and pearl shells are the principal articles exported; and cocoa-nuts are the general article of barter throughout the islands for calicoes, cotton cloth, knives, cordage, groceries, &c., which are imported chiefly from Tahiti. The exports from Tahiti, the principal island, amounted in 1863 to £21,960, and the imports to £75,888.

Tahiti is said to have been visited as early as 1606. Captain Cook reached it in 1769, and discovered many of the other islands of the archipelago, to which he gave the name of S. I., in honour of the Royal Society of London. In 1797, the first missionship fitted out by the newly formed London Missionary Society arrived at Tahiti. After 19 years of apparently fruitless labour, the influence of the missionaries began to be felt, and soon afterwards became so powerful as to be almost paramount. A quarrel between the Protestant and Roman Catholic missionaries, who thought it better to enter upon ground already occupied by Protestants than to take up new ground for themselves, occasioned the interference of France in favour of the latter, and the island of Tahiti was taken possession of in the name of Louis Philippe, by a strong French force in 1844. All the possessions of the native ruler—who, however, still enjoys nominal authority—were afterwards placed under the protection of France, and the S. I., though still nominally a protected state, may be considered as virtually a French colonial possession. Many of the Protestant missionaries left the island in consequence of the interference of the French authorities with their labours. Some, however, remained, and the congregations continued to meet. An application to the British government procured a concession on the part of the French government of some of the rights of religious liberty, which had been taken away by the local authorities.

SOCINUS, the name of two celebrated heresiarchs, uncle and nephew, who have given name to a sect of Christians, the Socinians, better known, however, as Unitarians (q. v.).—LÆLIUS SOCINUS, the elder of the two, was born at Siena, in Tuscany, in 1525, and belonged to a family that had long been distinguished for its cultivation of literature and science. His father, Marianus Socinus, was an able lawyer, and designed his son for the

same profession. But Lælius soon displayed a strong preference for theological inquiry, and in order to better prosecute his biblical studies, he made himself familiar with Greek, Hebrew, and Arabic. The only result of his legal training that one can discern is an obstinate aversion to believe anything 'unreasonable.' The principles of the Reformation had slowly found their way into Italy, and in 1546, a secret society was formed at Vicenza for the discussion of religious questions. It was composed of 40 persons, distinguished by their rank, their occupations, and their titles. S. was admitted a member. The conclusions at which they arrived were unfavourable to the dogma of the Trinity, which they held to have been borrowed by the early church from the speculations of Greek philosophers. The purpose of their meetings together having been discovered, the society broke up. Some of the members were arrested and put to death, others sought safety in flight. Among the latter was S., who travelled in France, England, Holland, Germany, and Poland, making the acquaintance, and acquiring the esteem, of many transalpine scholars, and finally settled in Zürich, where he died in 1562, when only 37 years of age. Lælius S., unlike most heretics, was a prudent and reticent man. His speech at least never bewrayed him; but in his correspondence with his Italian relatives and friends, he shewed himself an ardent and eloquent disputant, and made not a few proselytes. Once, in a moment of mistaken confidence, he disclosed himself to Calvin, who grimly warned him to get rid of his 'itch of inquiry,' lest he should 'draw on himself great torments.' In the same year occurred the murder of Servetus.—See Illgen's *Vita Lælii Socini* (Leip. 1814). and *Symbolæ ad Vitam et Doctrinam Lælii Socini* (Leip. 1826).

Socinus, Faustus, nephew of the preceding, was the son of Alessandro Socinus, and was also born at Siena, 5th December 1539. By the mother's side, he was very highly connected; but having lost his parents while still young, his education was carelessly conducted; and he himself, at a later period, lamented the imperfection of his scholastic culture. His want of learning, however, only induced him to speculate the more freely, and thus it happened, partly from native bias, and partly from his uncle's epistolary arguments, that Faustus was a heretic and anti-Trinitarian before he was out of his teens. In 1559, when only 20 years of age, he found it advisable to seek an asylum in France, and was living at Lyon when he got news of his uncle's death. He immediately proceeded to Zürich, and possessed himself of his relative's MSS., after which he returned to Italy. He entered the service of the Grand Duke of Tuscany, and during twelve years seemed to forget, amid the cares of office and the dissipations of a court, the thorny questions of theology. But at the expiry of that period, he was seized with a stronger desire than ever to investigate the truths of religion, and in spite of all remonstrances, proceeded to Germany—the centre of theological activity. In 1574, he retired to Basel, to prosecute his studies more closely; but a disputation which he had with a certain Fr. Pucci (1578), obliged him to leave Switzerland. At the request of George Blandrata, he visited Transylvania, where anti-Trinitarians were numerous, especially among the nobles, and eagerly sought (not without success) to make converts to his opinions. In 1579 he went to Poland. Anti-Trinitarianism was even stronger there than in Transylvania, and S. soon obtained a great influence. He preached, and disputed, and wrote with a zeal that Socinianism has seldom displayed since. His position in relation to the Reformers was, that Luther and Calvin had rendered great services to the cause of religion, but that they had not gone far enough, that the only solid basis on which Protestantism could rest was human 'reason,' that everything that contradicted it should be rejected as false and incredible, and that dogmas that were absurd should not be allowed to shelter themselves from criticism because their defenders chose to call them 'mysteries.' The Protestants were alarmed, and the ablest among them undertook publicly to confute Socinus. A disputation was held in the college of Posna, which ended in S. reducing all his opponents to silence; but they retaliated (after the unscrupulous fashion of the times) by trumping up against their vanquisher a charge of sedition, which, although ridiculously groundless, made it necessary for S. to withdraw from Cracow. While living in retirement on the estate of a Polish noble, Christopher Morsztyn, he married the daughter of his protector. She seems to have been a tender and affectionate wife; and when S. lost her in 1587, he almost broke his heart through grief. About this period, his property in Italy was confiscated; but he had powerful and wealthy friends in Poland, who proved generous to him in his needs. In 1588, he took part in the synod of Brest (on the borders of Lithuania), and combated all the principal dogmas of the church—the divinity of Christ, propitiatory sacrifice, original sin, human depravity, the servitude of the will, and justification by faith. In 1598, on the publication of his *De Jesu Christo Servatore*, his enemies stirred up the populace of Cracow against him; and S. was pulled from a sick-bed, and nearly murdered. Soon after, he left the city, and found a refuge with one of his friends in the village of Luclavie, where he died, 3d March 1604. S.'s works are no longer read; but his opinions have never wanted advocates in any Protestant country. He and his uncle may be regarded as precursors of that spirit of Rationalism which has rooted itself so deeply in the thought of the modern world.—See Przipcow's Life of S., prefixed to a collection of his works in the *Bib. Frat. Polonorum* (Amst. 1656); Bayle's article in the *Dictionnaire;* and Soulmin's *Memoirs of the Life, Character, &c. of F. S.* (Lond. 1777).

SOCLE, a plain plinth, forming a pedestal for the support of a statue, column, &c.

SO'COTRA, an island in the Indian Ocean, off the east coast of Africa, 140 miles north-east of Cape Guardafui. It is 70 miles long, 15 miles in average breadth, has an area of upwards of 1000 sq. m., and from 4000 to 5000 inhabitants, mostly Bedouins. The surface consists for the most part of a table-land of from 700 to 800 feet high, and low plains skirt the northern and southern shores. All the streams of the island, with the exception of a few rivulets, are dry at a certain season; but rain-water is collected in reservoirs, and in most parts water can be obtained by digging a few feet below the surface. Owing to the somewhat unfertile character of the soil, most of the districts are more adapted for pasture than for agriculture; but grain, fruits, and vegetables are grown in the eastern districts. The aloe plant and the dragon's-blood tree are the chief commercial products. S. is included in the Imamat of Muscat.

SOCRATES, the celebrated Greek philosopher, was born at Athens in the year 469 B.C. His father, Sophroniskus, was a sculptor; and he followed the same profession in the early part of his life. His mother, Phænarete, was a midwife, to which avocation he was wont to compare his own peculiar method of conversational teaching. His family was respectable in descent, but humble in point of

means. His physical constitution was robust to an extraordinary degree, enabling him to endure the hardest military service, and to live his own chosen life of superiority to all wants above the barest necessaries of life. While his ordinary diet was simple and abstemious, he could, on religious festivals or social occasions, drink more wine than any one else without being intoxicated. He had the usual education of an Athenian citizen, which included not only a knowledge of the mother-tongue, and readings in the Greek poets, but also the elements of arithmetic, geometry, and astronomy as then known. As a young man, he frequented the society of the physical philosopher, Archelaus (a disciple of Anaxagoras); but the philosophers that did most to determine his own special turn of mind must have been Parmenides and 'the double-tongued and all-objecting Zeno.'

Excepting in connection with his philosophical career, few circumstances of his life are known. He served as a hoplite, or heavy-armed foot-soldier, at the siege of Potidæa, at the battle of Delium, and at Amphipolis, and his bravery and endurance were greatly extolled by his friends. On two memorable occasions, he stood forward in political life. After the battle of Arginusæ, in 406, the ten generals in command were publicly arraigned for neglecting to obtain the bodies of the killed to receive the rites of interment. The clamour for their condemnation was so great, that the court wished to proceed in violation of the legal forms; but S., as the presiding judge, firmly refused to put the question. The other occasion was during the tyranny of the Thirty, who took up the policy of compelling a number of influential citizens to take a part in their illegal murders and confiscations; but S. withstood them at the peril of his own life.

Somewhere about the middle period of his life, he relinquished his profession as a statuary, and gave himself up to the career that made him famous. Deservedly styled a philosopher, he neither secluded himself for study, nor opened a school for the regular instruction of pupils. He disclaimed the appellation of teacher; his practice was to talk or converse, 'to prattle without end,' as his enemies said. 'Early in the morning, he frequented the public walks, the gymnasia for bodily training, and the schools where youths were receiving instruction; he was to be seen in the market-place at the hour when it was most crowded, among the booths and tables where goods were exposed for sale. His whole day was usually spent in this public manner. He talked with any one, young or old, rich or poor, that sought to address him, and in the hearing of all who chose to stand by. He visited all persons of interest in the city, male or female; his friendship with Aspasia is well known; and one of the most interesting chapters of Xenophon's *Memorabilia* recounts his visit to and dialogue with Theodotê—a beautiful *hetæra*, or female companion. Nothing could be more public, perpetual, and indiscriminate as to persons than his conversation; and as it was engaging, curious, and instructive to hear, certain persons made it their habit to attend him in public as companions and listeners. These men, a fluctuating body, were commonly known as his disciples or scholars, though neither he nor his personal friends ever employed the terms *teacher* and *disciple* to describe the relation between them.' —Grote's *Greece*, chap. lxviii.

Another peculiarity of S. was his persuasion of a special religious mission. He had been accustomed all his life to hear what he considered a divine voice, or preternatural sign, which came to him solely as a prohibition or warning, and never as an instigation to act. In deference to it, he had kept back from entering public life, and it caused him to refrain from premeditating the defence that he made on his trial. Nor was this all; relying, like his countrymen, on divine intimations by dreams and oracles, he believed that his mission had been signified to him by these. One oracular intimation in particular he described in his defence as the turning-point of his life. An admirer and friend of his, Chærephon, about the time when he began to have some repute as a wise man, consulted the oracle at Delphi as to whether any man was wiser than Socrates. The priestess replied: 'None.' The answer, he said, perplexed him very much; for he was conscious to himself that he possessed no wisdom on any subject, great or small. At length, he resolved to put the matter to the test by taking measure of the wisdom of other persons as compared with his own. Selecting a leading politician, accounted wise by himself and by others, he put a series of questions to him, and found his supposed wisdom was no wisdom at all. He next tried to demonstrate to the politician himself how much he was deficient; but found him impracticable on this head, refusing to be convinced. He then saw a meaning in the oracle, to the effect that his superiority to others lay not in his wisdom, but in his being fully conscious of his ignorance. He tried the same experiment on other politicians and rhetors, then on poets, and lastly on artists and artisans, and with the same result. Thereupon, he considered it as a duty imposed upon him by the Delphian god to cross-question men of all degrees as to their knowledge, to make them conscious of their ignorance, and thereby put them in the way of becoming wise. We shall see presently wherein this low view of the human intelligence differed from the contemptuous tone of a mere satirist.

The intellectual characteristics of S., through which he influenced the whole subsequent course of human thought, may be stated under three heads: 1. Subject, 2. Method, and 3. Doctrine.

1. As to Subject.—Here he effected a signal revolution, metaphorically expressed by the saying of Cicero, that 'Socrates brought down philosophy from the heavens to the earth.' The previous philosophies consisted of vast and vague speculations on nature as a whole, blending together Cosmogony, Astronomy, Geometry, Physics, Metaphysics, &c. S. had studied these systems, and they left on his mind a feeling of emptiness and unsuitability for any human purpose. It seemed to him that men's endeavours after knowledge would be better directed to the human relationships, as involving men's practical concerns. He could not go to any public assemblage without hearing questions agitated respecting the just and unjust, the honourable and base, the expedient and hurtful; moreover, he found that the opposing disputants were, without knowing it, very confused in their ideas as to the meanings of those large words in which the weightiest interests centred. Accordingly, he was the first to proclaim that 'the proper study of mankind is man;' human nature, human duties, and human happiness made up a field of really urgent and profitable inquiry. In astronomy, he saw a certain utility for navigation, and for the reckoning of time, to which extent he would have it known by pilots and watchmen; geometry was useful in its literal sense of land-measuring; arithmetic he allowed in like manner so far as practically useful; but general physics, or the speculations of philosophers, from Thales downward, as to the origin of all things out of water, fire, air, &c., he wholly repudiated. 'Do these inquirers,' he asked, 'think that they already know *human* affairs well enough, that they thus begin to meddle with divine? Do

they think that they shall be able to excite or calm the winds at pleasure, or have they no other view than to gratify an idle curiosity?' He considered it not only unprofitable but impious to attempt to comprehend that department. The gods, he thought, managed all those things after their own fashion, and refused to submit them to invariable laws of sequence, such as men might discover by dint of study; the only means of knowledge permitted was religious sacrifice and prayer, and the consultation of the oracles. While this was the appointed way in reference to divine things, it was equally appointed that human things should be learned by diligence in study and investigation.

2. In regard to Method, S. was the author of still greater innovations. It was to little purpose that men applied themselves to human affairs, if they conceived them loosely, and with no regard to evidence. S. introduced at least one element of logical precision into the handling of questions, by insisting on accuracy in Definition and Classification. His mode will be seen in the statement of Xenophon. 'Socrates continued incessantly discussing *human* affairs, investigating—What is piety? What is impiety? What is the honourable and the base? What is the just and the unjust? Men that knew these matters, he accounted good and honourable; men that were ignorant of them, he assimilated to slaves.'

His investigation thus took the form of ascertaining the exact meaning—that is, the definition—of the leading terms in ethics and in politics, the settling of what J. S. Mill calls the *connotation* of a general word, which determines how to apply it rightly to each individual case. The very idea of defining a general term, now so obvious, never seems to have suggested itself to any one previous to Socrates. And his manner of seeking out those definitions is also characteristic, and links itself to his conversational method, and his convicting men in general of ignorance in things that they thought they knew. Professing himself to be able to furnish no exact definition (this professed ignorance was called the Socratic irony) of justice, temperance, courage, &c., and finding every one else quite confident in their ability to supply the want, he asked some one to state his definition; and on its being given, he put a few further interrogations (as he said) by way of making sure that he understood the meaning, but with the speedy effect of driving the respondent into a humiliating self-contradiction. His method is most fully exemplified in certain of the Platonic dialogues, as the first *Alcibiadês*, *Lachês*, *Charmidês*, *Euthyphron*, &c. According to Xenophon, he could pass from his severe cross-examining method, with its humiliating shock of convicted ignorance, and address to his hearers plain and homely precepts, inculcating self-control, temperance, piety, duty to parents, brotherly love, fidelity in friendship, diligence, &c.—such direct admonitory influence being common to him with the so-called Sophists. He probably went beyond the ordinary teaching of the Sophists in exhorting men 'to limit their external wants, to be sparing in indulgence, and to cultivate, even in preference to honours and advancement, the pleasures arising from a performance of duty, as well as from self-examination and the consciousness of internal improvement.' This strain of exhortation, his manner of life in harmony therewith, and the virtual self-immolation of his death, may be considered as the conjoint root of the Cynic and the Stoic philosophies.

3. As regards Doctrine, S. was distinguished chiefly by his theory of virtue. Virtue, he said, consisted in knowledge. To do right, was the only road to happiness; and as every man sought to be happy, vice could arise only from ignorance or mistake as to the means; hence the proper corrective was an enlarged teaching of the consequences of actions.

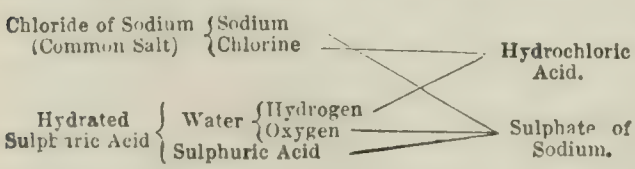
We cannot, on any fair interpretation of knowledge, regard this as other than a one-sided view. It takes note of one condition of virtue, since there can be no right conduct without understanding the tendency of actions, or, at all events, the meaning of rules; but it omits, what is also essential, the state of the emotions or dispositions, which may be directed either to exclusively self-regarding ends, or to ends involving also the good of others. There is an obvious connection between the doctrine and the Socratic analogy of virtue to the professions. The virtue of an artisan is almost exclusively contained in his skill or knowledge; his dispositions can usually, though not always, be depended on, through the pressure of his immediate self-interest. But the practice of S. was larger than his theory; for, as already remarked, his exhortations were addressed to men's feelings or sentiments as well as to their intellect. His political doctrines were biassed by the same analogy of special professions. The legitimate king or governor was he alone that knew how to govern well.

In the year 339 B. C., an indictment was laid against S., in the following terms: 'Socrates is guilty of crime: first, for not worshipping the gods whom the city worships, and for introducing new divinities of his own; next, for corrupting the youth. The penalty due is death.' The trial took place before a dikastery, or law-court, composed of citizen-judges, like our juries, but far more numerous; the number present seems to have been 557. His defence is preserved by Plato, under the title *Apology of Socrates*. The tone of it, so admirable to us, was such as to make acquittal all but impossible, from the number of enemies created by his cross-questioning annoyance of all classes of men, and from various other causes. He dwelt on his mission to convict men of ignorance for their ultimate benefit; pronounced himself a public blessing to the Athenians; declared that, if his life was preserved, he would continue in the same course; and regarded the prospect of death with utter indifference. By a majority of either five or six, the charges were declared to be proven. A vote had then to be taken on the sentence. By the Athenian practice, the accuser named a penalty, and the accused was asked to do the same; the judges were restricted to one or other of these. The accuser named death. S., maintaining the same high tone, declared at first that he deserved the highest public reward; but, on the instigation of his friends, he ended by proposing a trifling fine. The court, by a majority, decided for the capital sentence. There was an accidental interval of 30 days before the execution, during which S. in prison conversed with his friends as usual; on the last day occurred his conversation on the Immortality of the Soul, referred to in the Platonic dialogue called *Phædon*. He then drank the hemlock, and passed away with the dignity and calmness becoming his past life.

'There can be no doubt,' says Mr Grote, 'that the individual influence of Socrates permanently enlarged the horizon, improved the method, and multiplied the ascendant minds of the Grecian speculative world, in a manner never since paralleled. Subsequent philosophers may have had a more elaborate doctrine, and a larger number of disciples who imbibed their ideas; but none of them applied the same stimulating method with the same efficacy; none of them struck out of other minds that fire which sets light to original thought; none of them either produced in others the pains of intellectual

pregnancy, or extracted from others the fresh and unborrowed offspring of a really parturient mind.'—See Grote's *Greece*, chap. lxviii.

SODA. See SODIUM.



SODA, MANUFACTURE OF. Soda, or, more correctly, carbonate of sodium, occupies the chief place among our leading chemical manufactures, alike from its own importance, and also on account of its influence on other great chemical industries, such as glass-making, soap-making, bleaching, &c.

A native carbonate of sodium, or rather a sesquicarbonate, called Natron (q. v.), is found in Egypt and some other parts of the world. In Hungary, several manufactories exist for the purification of a native soda found there. Formerly, most of the soda in use was extracted from certain plants; and two kinds were known in commerce under the names of Barilla (q. v.) and Kelp (q. v.).

But the quantity of soda got from all other sources is now insignificant in comparison with that manufactured from common salt (chloride of sodium—see SODIUM). The process was invented by a Frenchman named Leblanc, and was first made known to the world by a commission of the French republic in 1794, although dating some years earlier. It is unquestionably the most valuable discovery in the entire range of chemical manufactures; and it has been practised for seventy years without any important alteration. It is sad to think that the author of this invention reaped no benefit from it himself, but spent the last of his days in an hospital, 'a wreck in fortune, health, and hope.' Owing partly to the war between France and England, and partly also to the existence of a duty of £30 per ton on common salt, which continued for eight years after the close of the war, Leblanc's process was not adopted in Great Britain till 1823; at least, any attempt to use it before that time was confined to making soda on a limited scale from brine. After the repeal of the tax in that year, Mr James Muspratt erected his celebrated works at Liverpool, adopted the process in its entirety, and succeeded, after overcoming many difficulties, in establishing in Great Britain a chemical manufacture which has since become the most important in the world.

The object of the soda-process is to separate the sodium of the salt, and unite it with oxygen to form caustic soda, or, what is much more generally done, to unite the sodium with both oxygen and carbonic acid to form carbonate of sodium. The several stages of the process are as follows:

First Operation—The Production of Sulphate of Sodium.—The decomposition of the common salt is effected by treating it with sulphuric acid, which transforms it into sulphate of sodium and hydrochloric acid. The following diagram illustrates the interchange of elements which takes place:

This operation was long conducted in a common Reverberatory Furnace (q. v.), and the hydrochloric acid was suffered to escape into the air. Not only was the acid thus lost, but it destroyed all vegetation in the neighbourhood of soda-works, and involved their owners in serious law-suits for damages. The great chimneys of the St Rollox Works, Glasgow, and Mr Muspratt's, Liverpool, which are nearly 500 feet high, were erected with a view of curing this evil, but they were found to be ineffectual. One of the most improved furnaces now in use for the purpose is shewn in figs. 1 and 2. They are built in pairs, and in the front part of each there

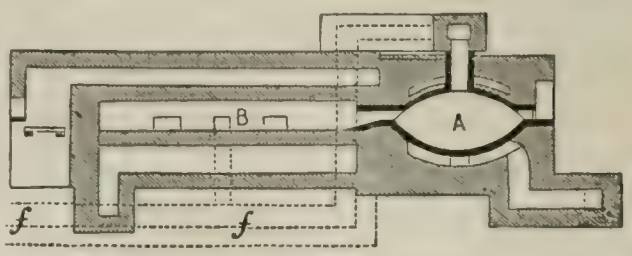


Fig. 1.—Plan of Decomposing Furnace.

is a shallow cast-iron pan A, nine feet in diameter, with a sheet-iron cover, and so built that the fire may act on the bottoms and sides. Behind this, an oblong brick-chamber, B, 30 feet by 9 feet, is situated, with separate fire-places, and called the salt-

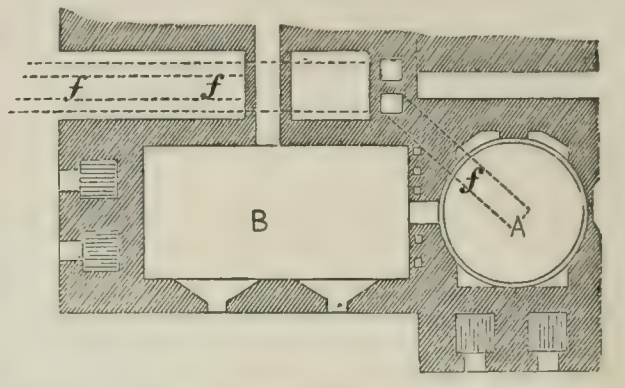

Fig. 2.—Vertical Section of Decomposing Furnace.

cake furnace. Acid flues, *f*, *f*, are led from each compartment of the double furnace into one main flue, which has its outlet into a condensing tower, to be presently described. Separate flues are also provided for the conveyance of smoke to a main chimney. The furnace is worked in the following way: when it is properly heated, salt to the amount of 10 cwts. is thrown in by an opening, and about 80 gallons of strong sulphuric acid are heated and run in. The mixture, which is well stirred with an iron rake, gradually thickens, and in about an hour the pasty mass, not yet all decomposed, is pushed through the opening into the salt-cake chamber, B. Here it is spread out on the sole, and maintained at a red heat for another hour, when the whole of the hydrochloric acid is expelled, and the conversion into sulphate of sodium complete. A pair of furnaces, about one-half larger than those above described, will produce about 19 tons of sulphate of sodium in a day, for which 16 tons of common salt are required. At the St Rollox Chemical Works, Glasgow, about 500 tons of common salt are decomposed weekly.

A very important part of this operation is the condensation of the hydrochloric acid gas, which is disengaged in large volumes during the decomposition of the salt. As already stated, it was formerly allowed to escape into the atmosphere. The acid flues convey it to the condensing towers (fig. 3), which are generally filled with pieces of burnt coke, through which a supply of water is kept running. The gas enters at the bottom of the first tower, passes upwards, and descends the second, and is gradually absorbed by the water, forming strong liquid acid, which is run out by openings at the bottom of the condenser. So perfect is the system of condensation now in use at some works, that of the acid produced by 100 tons of pure chloride of sodium which should yield 62 tons, as much as 58½ tons

have actually been collected; and it has been instanced, as a curious illustration of this in another way, that Mr Muspratt's great works,

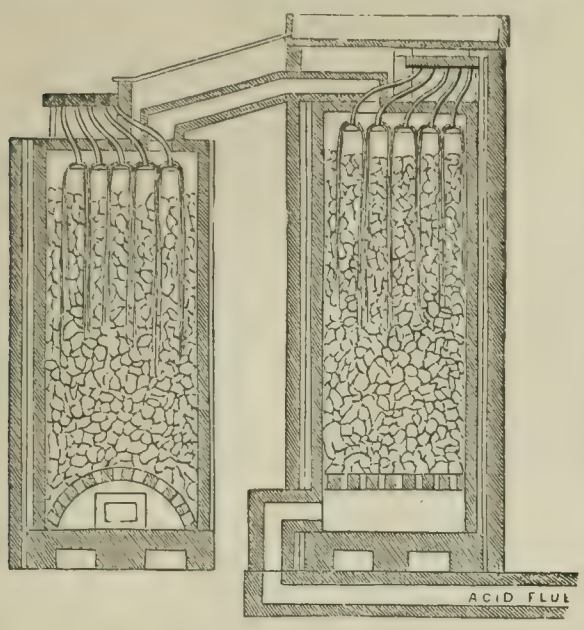

Fig. 3.—Section of Coke Towers for condensing the Hydrochloric Acid Gas.

which were at one time forced out of Liverpool as a nuisance, have been established there again without exciting any complaint, and even without many knowing it. Notwithstanding the perfection thus attained, some manufacturers were either not so careful or not so successful, and their works being still considered obnoxious to their neighbourhoods, an 'Alkali Act' was passed by parliament in July 1863, 'For the more Effectual Condensation of Muriatic (hydrochloric) Acid Gas in Alkali Works.' This act compels every manufacturer of alkali to secure the condensation of not less than 95 per cent. of the muriatic gas evolved in his works, under a penalty not exceeding £50. The hydrochloric acid obtained in this process is mostly used in the manufacture of bleaching powder.

Second Operation—The Conversion of the Sulphate of Sodium into Black-ash, called also Ball Soda.—This is effected by heating a mixture of sulphate of sodium, carbonate of lime, and coal, in a reverberatory furnace. The proportions now used are the same as those first recommended by Leblanc—viz., sulphate of sodium, 100 parts; carbonate of lime, 100 parts; carbon (charcoal), 55 parts. But as coal is employed in England instead of charcoal, the quantity used is generally 75 to 100 of each of the other two ingredients. The 'balling furnace' used in this operation is shewn in fig. 4. It has two beds, the one

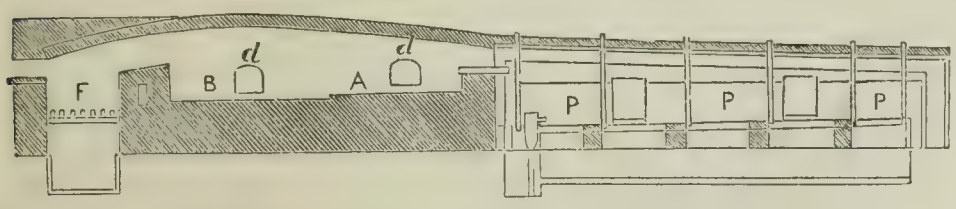

Fig. 4.—Section of Balling Furnace, shewing an evaporating pan for Soda-lye in connection with it.

being raised a few inches above the other. F is the fireplace, the waste heat from which is usually employed in boiling down the soda-lye as indicated in the section. The charge is thrown into the bed, A, of the balling furnace, after it has been raised to a bright red heat, and remains till it becomes sufficiently heated throughout the whole mass. It is then transferred to the *fluxing bed*, B, which is next the fire, and exposed to a higher heat, when it shortly begins to soften and flux into a mass like dough. The chemical changes now take place, and are indicated by many little flames of carbonic oxide termed 'candles' appearing; when these flames become less numerous, the transformation is complete. The charge is withdrawn in a red-hot state by the working door, and received into iron barrows, where it solidifies into blocks of crude soda, termed ball soda, or black-ash. Within the last year or two, a novel form of balling-furnace has been in operation at the Jarrow Chemical Works, South Shields. It consists of a revolving cast-iron cylinder lying in a horizontal position, 11 feet long by 7 feet in diameter, and lined with firebrick. It is said to heat more uniformly, to decompose the charge better, and to require less skilled labour in the working than the ordinary furnace; but its superiority on the whole is still in some measure disputed.

The theory of this process is involved in considerable obscurity, like many more chemical operations conducted on a large scale in highly heated furnaces: suffice it here to say, that the simplest view of the reactions is, that there is first a reduction of the sulphate of sodium to the sulphuret of sodium, by the action of the hot coal; and secondly, the conversion of the sulphuret of sodium into carbonate of sodium and sulphide of calcium by means of the heated chalk.

Third Operation—The Preparation of Carbonate of Sodium from the Black-Ash, by Lixiviation and Evaporation.—For some purposes the crude soda, or black-ash, is used without further purification; for example, in soap-making, in which considerable quantities are consumed. The lixiviation of the crude soda is effected by the use of a series of iron tanks, or vats, into which it is placed with water. The working of these vats will be most simply explained by the apparatus shewn in fig. 5. Several tanks,

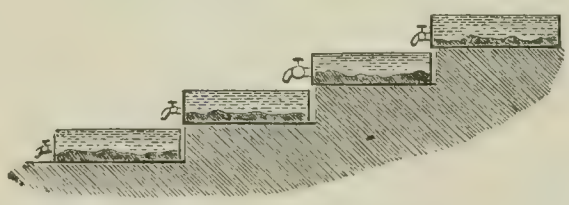

Fig. 5.—Apparatus for lixiviating the crude Soda.

each of the capacity of 600 gallons, rise above one another in successive stages, so that the liquor of the highest can be run into the next lower, and so on. The black-ash is introduced fresh into the lowest vat; it then passes from vat to vat, and is taken away exhausted at the highest one. The water, on the contrary, comes in fresh at the top, and in passing downwards encounters less exhausted ash in each succeeding vat, and finally passes away from the lowest a fully saturated solution. In most soda-works, the vats are now arranged differently, although the ash may be said to be exhausted in the same way. In the new arrangement, the vats are placed horizontally, and advantage is taken of the fact that solutions in becoming richer become also heavier, so that, although the tanks are all on a

level, the water runs through them with what is virtually a downward flow. We have not space to describe minutely this very elegant and economical plan; it will be enough to say that it completely obviates the necessity of lifting the ash from vat to vat, because any two contiguous ones can be made at pleasure the highest and lowest points, and, therefore, those of ingress and egress for the lixiviating fluid. 'Each vat, in due rotation, is emptied and refilled; and thus each in turn successively occupies the highest, lowest, and all intermediate points of the declivity.'

The next stage is the evaporation of the soda-lye, which is conducted in a variety of ways. A common method consists in using the waste heat of the balling furnace, the flame from which passes over the surface of the liquor, as shewn in fig. 4. With proper manipulation the soda falls to the bottom, and is raked out at intervals through a side-door, and drained upon a sloping surface. By another system, the lye is evaporated in pans where the heat is applied below, so as to preserve the liquor from contact with the gaseous products of combustion.

The soda-salts (chiefly carbonate of sodium), thus obtained by evaporation of the lye, contain caustic soda, which requires to be carbonated, and a little sulphate of sodium, which it is necessary to get rid of. They are accordingly transferred to a reverberatory furnace, and calcined, at a moderate heat, along with sawdust, or sometimes with small coal, the mixture being stirred with iron paddles. By this treatment, the caustic soda is converted into carbonate of sodium, the sulphur is mostly expelled, and we now obtain the *soda-ash*, or alkali of commerce, which generally contains about 50 per cent. of real soda, Na_2O; the other ingredients, besides the carbonic acid with which it is combined, being chiefly water, sulphur, and common salt. Sometimes it is further purified, and it is then known as *white alkali*.

Soda crystals, or what is commonly called 'washing-soda,' are obtained by dissolving the soda-ash in hot water, then filtering the solution and boiling it till the specific gravity reaches 1·3, when it is transferred to the crystallising coolers. Bars of wood or iron are laid across these vessels to sustain the mass of crystals which form, and in ten days at most the crystallisation is complete. Crystals of soda are purer than soda-ash, but they are of much less value, weight for weight, because of the large quantity of water which enters into their constitution, amounting to $62\frac{1}{2}$ per cent.

A new and daily-increasing branch of the soda-trade has sprung up within the last ten years—namely, the manufacture of Caustic-soda. For soap-making, bleaching, and several other purposes, the soda is always used in this state, so that, in those cases, the ordinary carbonate of soda requires to be rendered caustic by quicklime. Manufacturers have, accordingly, taken to the plan of treating the black ash-liquor with hydrate of lime, and so obtain caustic soda at this stage instead of sending it into the market as a purified carbonate of sodium, for purposes where it requires to be decarbonated again. Another plan consists in mixing a small quantity of chloride of lime, or nitrate of sodium, with the soda-lye from the black-ash. It is then concentrated into a strong solution and allowed to cool, which separates nearly all the foreign salts. The strong liquor is finally evaporated in round iron pots heated to redness.

Soda is now manufactured by the Pennsylvania Salt Company, at Natrona, near Pittsburg, Pa., and in the north of Germany from the mineral Cryolite (q. v.), which is a double fluoride of sodium and aluminium. It is found in enormous masses in Greenland, and nearly 8000 tons were imported into Philadelphia and New York in 1870.

There were, in 1865, 50 establishments in Great Britain, in which soda was manufactured by Leblanc's process, producing about 3000 tons of soda-ash, about 2000 tons of soda crystals, about 250 tons of bicarbonate of sodium, and about 400 tons of bleaching-powder per week. The total annual value of these products may be estimated as exceeding two millions sterling, the labour of more than 10,000 men.

The Pennsylvania Salt Company has imported annually since 1867 about 8000 tons. At Natrona, more than half a million of dollars have been invested, and employment given to 500 men. The various manufactures from Cryolite have a market value of $1,500,000. Caustic soda, Saponifier, or Concentrated lye, and pure alumina are the most valuable of these products. For the method of making carbonate of sodium, &c. from Cryolite, see *Rep. of Commissioners to Paris Exhibition*, 1867, Washington, 1869.

SODA-WATER. See Aërated Waters.

SO'DIUM (symb. Na, equiv. 23, spec. grav. 0·972) is one of the metals of the alkalies—its oxide being soda. Its properties closely resemble those of the allied metal, potassium. It is of a bluish-white colour, is somewhat more volatile than potassium, and further differs from that metal in having a higher fusing-point (about 208°), a greater specific gravity, and in not catching fire when dropped in water (unless the water is heated), although, like potassium under similar conditions, it partially decomposes it and liberates hydrogen; and at the same time communicates a strong alkaline reaction to the solution. If, however, a piece of unsized paper is placed on the surface of cold water, and the sodium be placed on the paper, the metal takes fire, and burns with a deep yellow flame. Strictly speaking, it is the liberated hydrogen rather than the metal which burns, the yellow tint (which is characteristic of the sodium compounds) being due to a little sodium volatilised by the heat, mixing and burning with the hydrogen. When heated in the air, it burns with its characteristic yellow flame, and is converted into soda. When exposed *in vacuo* to a red heat it assumes the form of vapour, and admits of distillation. Like potassium, it must be kept immersed in naphtha, so as to exclude the oxidising action of the air. As a reducing agent, it is little inferior to potassium, and as its combining power is lower, and it is obtained much more cheaply, it may usually be advantageously substituted for potassium in reducing operations. Sodium does not occur in the metallic form in nature, but its compounds are very widely distributed. It is found by far the most abundantly in the form of chloride of sodium (or common salt), but it likewise occurs as albite or soda-felspar, cryolite (the double fluoride of sodium and aluminium, and the principal source from whence aluminium is procured), borax (the biborate of sodium), trona (the sesquicarbonate of sodium), and Chili saltpetre (nitrate of sodium).

The methods of obtaining sodium are similar to those already described for obtaining potassium. The following procedure recommended by Deville is regarded as the best for obtaining it in large quantity. Intimately mix 717 parts of dried carbonate of sodium with 175 parts of finely powdered charcoal and 108 parts of finely ground chalk, knead them into a stiff paste with oil, heat them in a covered iron pot till the oil is decomposed, and finally distil them in an iron retort with the precautions which are noticed in describing the preparation of Potassium (q. v.). The object of adding the chalk is to prevent the separation of the charcoal from the carbonate of sodium

when the latter fuses. This mixture ought to yield nearly one-third of its weight of sodium.

With regard to the history of sodium, it is sufficient to observe that Duhamel, in 1736, discovered that potash and soda (now known to be the oxides of potassium and sodium) were distinct bodies. Sir H. Davy first obtained the metal *Sodium* in 1807. The symbol of this metal, Na, is the abbreviation of *Natrium*, which is derived from *Natron*, one of the old names of native carbonate of sodium.

Sodium combines with all the elementary gaseous bodies, and two of these combinations—viz., those with oxygen and chlorine—are of extreme importance and value.

With *oxygen*, sodium forms two compounds—viz., protoxide (Na_2O) and a dioxide (Na_2O_2). The latter, being of no practical value, may be passed over without notice. The oxide (soda) was formerly known as *fossil* or *mineral alkali*, to distinguish it from potash, which, from the source from which it was procured, was termed *vegetable alkali*. Anhydrous soda (Na_2O) is procured by burning the metal in dry air; it is of a yellowish-white colour, powerfully attracts moisture, and retains the water so firmly that it cannot be expelled by heat. Hydrated or caustic soda (NaHO) closely resembles, both in its properties and in the mode of procuring it, the corresponding potash compound. It is, however, not so fusible as the latter, and is gradually converted, by exposure to the air, into carbonate of sodium, which is also an infusible salt in its anhydrous state. Solution of hydrate of sodium (or soda lye) is largely employed in the arts. It is prepared by boiling a tolerably strong solution of carbonate of sodium in milk of lime until a portion of the filtrate ceases to effervesce on the addition of an acid. The solid hydrate has a specific gravity of 2·13, and the quantity of anhydrous soda in any solution may be pretty closely approximated to by determining the specific gravity of the fluid at a temperature of 59°. Tables for this purpose have been constructed by Dalton (quoted in Miller's *Inorganic Chemistry*, 2d ed. p. 37) and by Zimmerman (reprinted in the article 'Sodium' in Knight's *English Cyclopædia*): they are also given in Watts's *Dict. of Chemistry*, art. *Sodium, Hydrate of.*

Many of the combinations of the oxide of sodium (soda) with acids—constituting soda-salts—are of great importance. Carbonic acid forms three salts with soda—viz., a normal carbonate, a sesquicarbonate, and a bicarbonate of sodium.

The *Normal or Ordinary Carbonate of Sodium* ($Na_2CO_3. + 10H_2O$), popularly known as the *Soda* of commerce, is a colourless, inodorous salt, with a nauseous alkaline taste. It crystallises in large transparent rhomboidal prisms, which contain nearly 63 per cent. of water, but it readily parts with all this water on the application of heat. The crystals also lose the greater part of their water on mere exposure to the air, when they effloresce, and fall to powder. Water at 60° dissolves half its weight of the crystals, and boiling water considerably more, the solution acting like an alkali on vegetable colours. This salt occurs native in the natron-lakes of Hungary, Armenia, &c., in association with sulphate of sodium and chloride of sodium. In other regions it appears in an efflorescent form on the surface of the earth. It is now, however, almost entirely manufactured from sea-salt. See SODA, MANUFACTURE OF.

Sesquicarbonate of Sodium ($Na_4H_2C_3O_9 + 2H_2O$) occurs native in the form of large, hard, non-efflorescent prisms, in Hungary, Egypt, Mexico, &c., under the name of *Trona* or Natron. When strongly heated, it loses one-third of its carbonic acid, and becomes converted into the preceding salt.

Bicarbonate of Sodium ($NaHCO_3$) may be formed by passing a current of carbonic acid through a strong solution of carbonate of sodium, till saturation takes place, and allowing the mixture to crystallise; or it may be produced on a large scale by exposing crystals of carbonate of sodium to a prolonged current of carbonic acid. The bicarbonate crystallises in four-sided prisms, which require 10 parts of water at an ordinary temperature for their solution. This salt is used largely in medicine. See AERATED WATERS.

Sulphuric acid forms with sodium a normal and an acid sulphate.

The *Normal or Ordinary Sulphate of Sodium* (Na_2SO_4) has already been described under its synonym of *Glauber's Salt* (q. v.). The acid salt, or *bisulphate* of sodium ($NaHSO_4$), is of no special interest.

The *Hyposulphite of Sodium* ($Na_2S_2O_3.5H_2O$) occurs in large, colourless, striated, rhombic prisms, of a cooling and sweet taste. When strongly heated in the air, it burns with a blue flame. It dissolves readily in water, depositing sulphur if the solution be kept in a closed vessel. It may be obtained by digesting a solution of sulphite of sodium on powdered sulphur. The sulphur is gradually dissolved, and forms a colourless solution, which on evaporation yields crystals of hyposulphite of sodium. This salt is largely employed in photography, and is occasionally prescribed medicinally. Sulphurous acid forms two salts with sodium—viz., a sulphite and a bisulphite. The *Sulphite of Sodium* ($Na_2SO_3.7H_2O$) is obtained by passing sulphurous acid over carbonate of sodium, dissolving the resulting mass in water, and crystallising; when the salt is obtained in efflorescent oblique prisms, which fuse at 113°, and are soluble in 4 parts of cold water, the solution having a slightly alkaline reaction, and a sulphurous taste. This compound is commercially known as *Antichlore*, and is largely used in paper-manufactories for the purpose of removing the last trace of chlorine from the bleached rag-pulp. The *Bisulphite* is of no importance. *Nitrate of Sodium* ($NaNO_3$), known also as *Cubic Nitre* or *Chili Saltpetre*, occurs as a natural product on the surface of the soil of certain South American districts. In most of its properties, excepting its crystalline form, and further in its being deliquescent, it resembles nitrate of potassium. It is used to a considerable extent as a manure. The *Phosphates of Sodium*, though comparatively numerous, do not call for notice here. See PHOSPHATES. *Hypochlorite of Sodium* (NaClO) is at present only known in solution, in which it occurs as a yellowish-green fluid, evolving a smell of chlorine; it has strong bleaching power, and, when boiled, becomes decolorised, and evolves chlorine freely. It is formed by passing a stream of chlorine gas through a solution of carbonate of sodium, the resulting solution containing the hypochlorite, together with undecomposed carbonate of sodium and chloride of sodium. This is *Labarraque's* solution, and is useful as a bleaching agent, as an oxidising agent, and as a disinfectant agent. There are two *Borates of Sodium*, of which the only important one, the *Biborate*, is already described under its ordinary name of *Borax* (q. v.). Various *Silicates of Sodium* have been formed. In reference to the properties of these salts, see the articles FUCHS'S SOLUBLE GLASS and GLASS.

The *Haloid Salts* of sodium resemble, in their general characters, the corresponding salts of potash Of these, by far the most important is *Chloride of Sodium* or *Common Salt*, formerly known as *Muriat of Soda* (NaCl). It occurs naturally in far greater quantity than any other soluble salt. See ROCK-SALT, SEA, WATER. The following are its leading

properties: It crystallises in colourless, transparent cubes, which are anhydrous, soluble in about 3 parts of cold water, and scarcely more soluble in boiling water. A saturated solution has a specific gravity of 1·205, the specific gravity of the salt being 2·125. It is insoluble in pure alcohol, is inodorous, and has a purely saline taste, unmingled with bitterness, unless chloride of magnesium be mixed with it. At a red heat, it fuses, and becomes converted into a transparent brittle mass. The well-known decrepitation which occurs when salt is thrown on the fire, or otherwise strongly heated, results from the sudden expansion of water mechanically entangled amongst its particles. The uses of this salt have been known from the earliest times. It is an essential constituent of the food both of man and animals. From want of space, we must refer our readers to Liebig's *Letters on Chemistry* (Letter xxviii.) on this subject, in which the functions of salt in the food and in the blood are clearly pointed out. It is regarded as a necessity even by the rudest nations. 'In several countries of Africa, men are sold for salt; amongst the Gallas and on the coast of Sierra Leone, the brother sells his sister, the husband his wife, parents their children, for salt; in the district of Accra (Gold Coast), a handful of salt, the most valuable merchandise after gold, will purchase one, or even two slaves.'—Note to Liebig's *op. cit.* p. 413. Chloride of sodium is employed in the process of salting meat, in consequence of its powerful antiseptic properties. Meat thus prepared loses, however, a considerable portion of its nutritive juices, which pass into the brine; and is less digestible than in its natural state. Amongst the purposes for which this salt is mainly employed may be mentioned the manufacture of the various salts of sodium, especially the carbonate; the preparation of hydrochloric acid; the glazing of stoneware; the preparation of soap; &c. The other haloid salts—the iodide, bromide, and fluoride of sodium—require no notice.

Sodium has been recently found to enter into various groups of organic bodies. We shall take the sodium-alcohols as an example. When sodium or potassium is gradually added to anhydrous alcohol, the temperature rapidly rises, the metal is dissolved, hydrogen is evolved, and a fusible deliquescent compound is formed, which has received the name of *Sodium-alcohol* (or potassium-alcohol), or of *ethylate of sodium* (or potassium), its composition being such that it may be regarded as alcohol in which one atom of hydrogen is replaced by one of the metal; as shewn in the equation:

$$\overbrace{C_2H_5.H.O}^{\text{Alcohol.}} + NaO = \overbrace{C_2H_5.Na.O}^{\text{Sodium-alcohol.}} + H_2O.$$

The action of sodium or potassium on the other alcohols is of an analogous nature.

The *tests* for the salts of sodium are not very satisfactory, because the metal forms scarcely any insoluble compounds. A salt of sodium is usually concluded to be present when, the absence of all other bases having been proved, a saline residue remains, which, with bichloride of platinum, yields yellow striated prisms ($Na_2Pt^{iv}Cl_6.6H_2O$) by spontaneous evaporation. Before the blowpipe, the salts of sodium are known by the intense yellow which they communicate to the outer flame, and if a weak alcoholic solution of one of the salts is burned, a similar yellow tint is communicated to the flame. Spectrum analysis is too delicate to be of much practical use. Bunsen estimates the amount of soda that may be thus detected at the 195,000,000th part of a grain; and considering how universally diffused chloride of sodium is, this fractional amount is hardly likely to be absent.

In conclusion, the *medicinal uses* of the sodium compounds require our notice. They will be considered alphabetically. *Acetate of Sodium* is a mild diuretic, similar in operation to acetate of potash, for which it may be substituted. It may be given in doses varying from a scruple to a couple of drachms. *Arseniate of Sodium* ($Na_2ASO_4.14H_2O$) is serviceable in periodic affections, chronic skin-diseases, and the cases in which arsenic is generally employed in medicine. It has all the advantages of arsenite of potash, and seems to cause less irritation of the stomach. It is best given in the form of *Pearson's Solution*, which consists of one grain of the crystals of this salt dissolved in ten drachms of distilled water. Dose, from 20 minims, very gradually increased to two drachms, three times daily. The *Liquor Sodæ Arseniatis* of the Pharmacopœia is much stronger; its dose being from three to ten minims. Paper impregnated with a solution of arseniate of sodium sweetened with sugar is sold as a poison for flies. *Biborate of Sodium*, or *Borax*, is employed principally as a topical astringent, and is used with advantage in aphthous eruptions of the mouth and throat. *Bicarbonate of Sodium* is a most popular remedy in cases of dyspepsia, but its use is highly injurious when there are phosphatic deposits in the urine. See PHOSPHATIC DIATHESIS. Neligan strongly recommends the external application of an ointment consisting of 20 or 30 grains of the bicarbonate, with an ounce of cold cream, in cases of papular and vesicular eruption of the scalp. *Carbonate of sodium* is not employed as an antacid so frequently as the bicarbonate, in consequence of its disagreeable taste; but in the dried state, when deprived by heat of its water of crystallisation, it is much used as an alterative. In dyspepsia attended with acidity, a combination of the dried carbonate with blue pill and rhubarb pill is often extremely useful. As it has a very acrid taste, it should be combined, if given in powder, with some bland substance, such as Compound Tragacanth Powder. *Solution of Chlorinated Sodium* (known also as *Solution of Chloride of Sodium*, *Chlorinated Sodium*, *Hypochlorite of Sodium*, and *Labarraque's Disinfecting Liquor*) is preferable to hypochlorite of lime in destroying noxious effluvia, as the salt which is left does not deliquesce, while chloride of calcium is very deliquescent. It may be applied locally to foul ulcers, either in lotion (2 drachms to 8 ounces of water), or as a poultice with linseed meal and boiling water. *Phosphate of Sodium* ($Na_2HPO_4.12H_2O$), known also as *Tasteless Purging Salt*, is a mild saline purgative, with a far less unpleasant taste than sulphate of magnesia. It is especially adapted as a purgative for persons affected with deposits of red gravel (lithic or uric acid) in the urine. The dose varies from half an ounce to two ounces, and it may be given in broth, to which it imparts only a saline taste. *Sulphate of Sodium* and *Tartrate of Sodium and Potassium* have been already described under their ordinary names of *Glauber's Salt* (q. v.) and *Rochelle Salt* (q. v.).

SODOM AND GOMO'RRAH, two ancient cities of Syria, almost invariably spoken of in conjunction in the Bible, and forming with Admah, Zeboiim, and other towns, the 'cities of the plain,' which, on account of the enormous wickedness of their inhabitants (the nature of which is indicated in the term Sodomy), are said to have been overthrown — not submerged — by some terrible convulsion of nature. Modern writers on sacred topography are not agreed as to the precise site to be assigned to these cities, no trace of which now remains; the majority holdin

that they stood on the southern shore of the Dead Sea, near the salt hill of Usdum; while others, again, apparently with more countenance from the Scripture narrative (Gen. xiii. 10—13), maintain that Sodom, Gomorrah, and the other 'cities of the plain,' stood in the 'circle or plain of the Jordan,' east from Bethel and Ai, near where the river discharges itself into the Dead Sea. The popular belief, that the cities were miraculously overwhelmed by the waters of the Dead Sea, and that their remains may still be seen at the bottom, is an idle tale of superstitious travellers, uncountenanced either by fact or by the terms employed by Scripture to describe the catastrophe.

SODOM, APPLE OF, the name given to the fruit of a species of *Solanum* (q. v.). But it seems that the true APPLE OF SODOM, or MAD APPLE, of the shores of the Dead Sea, mentioned by Strabo, Tacitus, and Josephus, and described as beautiful to the eye, but filling the mouth with bitter ashes if tasted, is a kind of gall, growing on dwarf oaks, and produced by a species of gall-insect, which has received the name of *Cynips insana*. These galls are about 2 inches long, and 1½ inch in diameter, of a beautiful, rich, glossy, purplish-red colour, and filled with an intensely bitter, porous, and easily pulverised substance, surrounding the insect. They are attached to the twigs in a curious manner, different from other galls, the narrow end 'rising upwards on each side, and bending inwards, so as to clasp the extremity of the twig somewhat like a pair of wide and curved nippers.'

SODOMY, an unnatural crime, is punishable with penal servitude for life, or any term not less than ten years, and the attempt to commit it is punishable with penal servitude from three to ten years. In Scotland it is still nominally a capital offence, but never punished except by penal servitude and imprisonment.

SODOR AND MAN, BISHOPRIC OF. See HEBRIDES.

SOEST (pronounced SOHST), a town of Prussia, province of Westphalia, 36 miles south-east of Münster by railway, was, during the middle ages, a Hanse-town and fortress, and, in point of commercial importance, one of the foremost cities of Germany, with a pop. of from 60,000 to 70,000. Now, however, it is only the shadow of its former self; but relics of its ancient splendours still survive in its numerous and magnificent churches, of which the finest is the 'Meadow Church,' restored in 1850. Its municipal law, the *Jus Susatense*, was the oldest in Germany, and served as the model for the other imperial free-towns, Lübeck, Hamburg, &c. At present, S. has some trade in corn, and extensive breweries. Pop. 11,970.

SOFA'LA, or, as the old geographers sometimes wrote it, CEFOLA, is the name given rather indefinitely to that portion of the south-east coast of Africa extending from the Delta of the Zambezi (Quama of old geographers) as far south as the Rio Maneci or Delagoa Bay, or from lat. 18° to 26° S., although some modern geographers consider Cape Corrientes as its southern limit. This stretch of coast now comprehends the Portuguese captaincies of Rio de Senna, Tetè, Sofala, and Imhambane, besides the regions round Delagoa Bay, nominally under the control of the crown of Portugal, the extent inland being generally limited by the mountain region which runs parallel to the coast of Southern Africa, and forming a belt of low country about 150 miles wide, full of swamps, densely wooded, and generally unfavourable to European life.

S., in common with the remainder of the coast of Eastern Africa, was conquered by the Arabs between the 8th and 12th c.; it was visited in 1480 by Pedrao Cavalho, a Portuguese captain, from Abyssinia, before the route by sea to India was discovered. In 1500, the Portuguese, under Albuquerque, commenced making settlements on this coast, and built a strong fort on an island in the mouth of the Rio de Sofala, near a town which was founded 200 years before by the Arabs, and which still exists, although in a very decayed state. The inland region at the back of the coast district, now occupied by the Transvaal Boers towards the south, or by Moselikatse and his Amatabele to the north, and stretching away northward for an indefinite distance, formed the celebrated though mythical empire of Monomotapa, the accounts of which by the early travellers are perfectly marvellous. S. was considered by the old geographers as a very rich, gold-producing country, and was judged by some to be the Golden Ophir to which King Solomon every three years sent a fleet of ships; and, indeed, it seems to have derived its name from the Greek *Sophira*, by which Ophir is translated in the Septuagint. Lopez tells us that in his time the inhabitants related that the gold-mines of S. afforded yearly two millions of metrigals—every metrigal accounted for a ducat. Whatever may have been its former reputation, S. has long ceased to be a gold-producing country to any considerable extent.

An old writer says: 'Great wild elephants overspread the country, which the natives neither know how to tame nor manage; nor are lions, bears, stags, or harts and boars fewer; besides, sea-horses sport themselves in the Quama.' This description is pretty accurate, even at the present day, if we omit the bears, and call the stags antelopes; for the elephants, rhinoceroses, and other large game, driven away from the highlands in the interior by the pursuit of the Cape hunters, have descended into the coast lowlands, where the dense bushy nature of the country, and its extreme unhealthiness, protect them from extermination, although such keen sportsmen as M'Cabe, Chapman, and Edwards have not feared to follow them there.

The most northern regions of S. are the captaincies of Rio de Senna and Tetè, formerly called Matuka, which include the country on the right bank of the Zambezi, sloping down from the Malappo Mountains, which bound its basin on the south. The principal places are Tetè, in lat. 16° 12′ S., long. 31° 50′ E.; and Senna, in lat. 17° 30′, long. 34° 40′. The middle region comprises the captaincy of S., the seat of government being at the town or fort of that name, in the Bay of Massangane; lat. 20° 12′, long. 34° 40′. Imhambane is the name of the most southerly captaincy, in lat. 23° 51′, and long. 35° 20′. There are other inconsiderable Portuguese factories along the coast at Imhampoora, south of Imhambane, Mambone, and Lorenco Marquez, in Delagoa Bay, where a Portuguese governor resides.

Although nominally under Portuguese rule, yet the authority of that government rarely extends outside of the walls of the miserable forts held by its agents. It is computed that on the whole of the Portuguese settlements on the east coast of Africa there are not more than 500 colonists of European birth. Trading-parties of Dutch Boers from the Transvaal Republic occasionally visit the factories at Imhambane, Sofala, and Lorenco Marquez, to purchase articles of European manufacture in exchange for ivory, wax, timber, &c. The natives, generally, are of the negro type, gradually approximating to the more intellectual Zulu Kaffir as we proceed from the Zambezi to Delagoa Bay.

The principal exports from this region are ivory, bees-wax, hides, and rhinoceroses' horns; while a considerable clandestine traffic is said to be carried on in slaves. Considerable amounts of gunpowder, lead, coffee, and European clothes find their way up from the coast to the Boer settlements in the highlands of the interior. The coast-line is generally low and sandy, and dangerous on account of shoals and sandbanks. A group of islands, called Bazaruta, lie off the coast north of Cape St Sebastian, in lat. 22° S. The best harbour is that of Imhambane, and ships may ascend to the town, about 8 miles from the mouth of the river. The harbour at the mouth of the Rio de Sofala is difficult of access on account of its bar.

SOFFIT, a small ceiling, formed into panels, as over windows, ingoings of doors, staircases, &c.

SOFTENING AND INDURATION are terms used to express a pathological diminution and augmentation of the consistence of the tissues or organs of the body. These changes may arise from inflammatory action; but softening may also be induced by causes totally distinct from inflammation, as, for example, from a deficient supply of blood, from scrofula or cancer, or from long-continued functional inactivity (as in the case of paralysed muscles). Amongst the parts liable to both softening and induration are the brain and spinal cord, the heart, the lungs, the serous and mucous membranes, the liver, the spleen, the kidneys, the uterus, and the bones and cartilages.—For further details on the subject, the reader may consult the English translation of Vogel's *Pathological Anatomy*.

SOFT-GRASS (*Holcus*), a genus of grasses having a lax panicle, two-flowered spikelets, with two nearly equal glumes. The species are not numerous. The English name is derived from the soft and abundant pubescence of the British species, which are two in number, CREEPING S. (*H. mollis*), and WOOLLY S. or MEADOW S. (*H. lanatus*), both perennial grasses, and both very common. Meadow S. is found most abundantly on damp, moorish, or peaty soils, on which it is sometimes sown, as it yields abundant herbage; but it is very inferior to some other grasses, and therefore unsuitable for rich meadows and pastures. Creeping S. is generally found on dry, sandy, or other light soils; and very much resembles Meadow S., but is still more downy, and of smaller size. The roots sometimes extend 5 or 6 feet in a season. The roots contain much nutritious matter, and are a very acceptable food to horses and cattle, but especially to hogs, which grub them up for themselves when they have opportunity.

SOIGNIES, a town of Belgium, province of Hainault, 22 miles south-west of Brussels by railway. Its church of St Vincent Maldegaire, founded in the 10th c., if not earlier, is probably the oldest in Belgium. S. has breweries, distilleries, trade in stone and lime, and large fairs. Pop. 6873.—Some miles to the north-east, in the province of South Brabant, lies the forest of S., at whose southern extremity is situated the famous field of Waterloo.

SOILS consist of the disintegrated materials of the hard crust of the earth, mixed with decayed vegetable matter. This disintegration is effected partly by the chemical action of oxygen, carbonic acid, and the other acid or alkaline substances brought by the atmosphere to bear upon rocks, and partly by the wearing action of water in a fluid state or in the form of glaciers, or by its bursting force when frozen in deep clefts. The soils produced by running water, floods, and tides, are found along the banks or at the mouths of rivers, and are generally called *alluvial soils;* those produced by glacier-action are known as *drift soils;* and both are generally found at a great distance from the rocks of whose disintegrated materials they are composed. But by far the greater mass of soil has been produced in the other way above mentioned, by the gradual weathering of rock under atmospheric influence; and it is generally found adjoining or overlying the rocks from which it has been produced. Immediately beneath the soil or stratum of earth which affords nourishment to plants, is a mass of earth or rock, unmixed with decayed vegetable matter, to which the term *subsoil* is applied. The subsoil may or may not be similar in its geological constitution to the soil; and from the absence of vegetable matter, is generally lighter in colour than the latter.

Every species of rock has produced its soil; but the older formations, from their greater hardness and power of resistance to atmospheric action, produce, in proportion to their exposed surface, less soil than do the Secondary and Tertiary groups. The fertility of soils has no relation to the chronological succession of the strata of the earth's crust; thus, igneous rocks produce a naturally fertile soil, though they seldom become thoroughly disintegrated; metamorphic or transition rocks furnish one of poor quality, as does also the greater portion of the Silurian system; while to the vast mass of the Secondary group of deposits, especially the Devonian system, with its old red sandstone, and limestone, and marl beds, the mountain limestone of the Carboniferous system, and the new red sandstone of the Permian and Triassic systems, belong some of the richest tracts in Great Britain, though numerous members of the same group supply barren and ungrateful soils. The Lias, and Oolitic, and Wealden systems generally supply clay-soils of considerable fertility, but of the densest texture and most intractable character; soils formed from the cretaceous group are extremely variable in quality; but when the chalk is largely mixed with sand or clay, they exhibit a considerable degree of fertility; however, they have one great general defect, that of not sufficiently retaining moisture. The soils produced from the Tertiary formations possess no general characteristics, being sometimes extremely fertile, and again almost wholly barren; and, in short, we are bound to come to the conclusion, that the mere geological composition of soils affords no very reliable criterion by which their economic value can be estimated; the same rock which produces the almost barren soil of Argyleshire, weathers into the fertile soil of the Channel Islands; and to the old red sandstone are due at once the rich soil of Hereford, Monmouth, Moray, and Strathmore, and some of the most barren heaths and moors in Scotland. These apparent anomalies are no doubt largely produced by the various action of heat, moisture, and other meteorological agencies.

But however soils may vary in a geological point of view, they are all resolvable into a few elements—viz., the various compounds of aluminium, iron, manganese, the four alkaline metals, the seven alkaline earths, and the four organic elementary substances. These 18 bodies supply singly, or in combination, all the constituents necessary to the growth of plants, each of them having its own portion of the plant to sustain—the silica producing strength and rigidity in the stems; alumina giving tenacity to the soil, and so rendering it a stable support; magnesia perfecting the seeds; iron absorbing oxygen and ammonia from the atmosphere, and giving it up as required; and so on. Of these ingredients, silica, alumina, lime, along with matter derived from organic bodies, constitute the bulk of the soil; the other ingredients existing only

in minute quantity, and hence is derived the common quadruple division of soils into *silicious or sandy, argillaceous or clayey, calcareous*, and *humous*.

It is not sufficient that soil possesses all the ingredients necessary for rendering it fertile, or that these ingredients are in a sufficiently comminuted state to enable them to be absorbed; there is besides a certain physical or mechanical condition necessary. Thus, for example, a soil which possesses too great a proportion of silica, is too little retentive of moisture, and has not sufficient consistency of texture to be an effective support of tall plants; one in which calcareous matter abounds is also too dry a soil; while if alumina predominates, it is generally too retentive of moisture; and a great excess of the last-named ingredient renders it so extremely tenacious, as to be almost incapable of reduction to a proper mechanical state. The soil which is physically most perfect is composed of about equal proportions of the two great ingredients, silica and alumina, and is generally known as *loam*, being distinguished into *clay loam* or *sandy loam*, according as the alumina or silica sensibly predominates. But the physical qualities of soils do not wholly depend upon their composition; they are also largely affected by the depth of the soil itself, and the quality of the subsoil. Should the soil and subsoil be both retentive, or both porous, the defects of these states as to dryness or moisture are considerably increased; if porous and retentive soils of good depth rest upon subsoils of a contrary character, the defects of the former are to a considerable degree amended. But the advantages and disadvantages of these conditions must to a very large extent be judged by the prevalent character of the climate, a somewhat porous subsoil in a cold moist district being generally preferable, and *vice versâ*. Each of these classes of soils, when possessed of the chemical ingredients in quantity sufficient for the wants of plants, and of a texture favourable to their growth, excels in the production of certain species. Thus, the clay loams are unequalled for the production of wheat and beans; the sandy loams for barley, rye, and the various root-crops; while both are well suited for the growth of the other cultivated plants, or for perennial pasture.

Besides the calcareous and marly soils which may be, according to circumstances, classed as a clayey or sandy soil, rarely the former, there is the humous soil, which possesses characteristics peculiarly its own. It is not devoid of consistency like the sandy, or retentive of moisture like the clayey soils, but in its natural state is spongy and elastic in texture, of a remarkably dark colour, and when dried, becomes inflammable, and even when much improved by culture, retains these characteristics in a considerable degree. It consists wholly, or to a great extent, of vegetable matter, and is found in perfection in forests of ancient date, as the woods of America, and in the peculiar form of Peat (q. v.) in many parts of the world. In its ordinarily decomposed condition, it is at once the richest of soils; but in the state of peat it calls for long-continued drainage, and the application of decomposing agents, before it can be rendered of service in the production of crops.

Improvement of a soil must, then, as is seen from the foregoing considerations, be effected either by supplying the substances required by plants to a soil which is deficient in them, by altering its depth and texture, and by removing excess, or supplying deficiency of moisture. The first of these objects is effected by the introduction and incorporation of Manures (q. v.) with the soil, care being taken that the manure contains the requisite ingredients, and in such a condition as to be assimilable by plants either directly or indirectly through the soil, and by the more thorough exposure of the soil to the action of the atmosphere; the second is effected by the admixture of marl or clay with sandy, chalky, or peat soils, of lime, ashes, or burned clay, with tenacious clay soils, or by the mixture of the subsoil (if differing in quality) with the soil by means of the subsoil plough, or by more complete surface-tillage, and free exposure to the action of frost; and the third is accomplished by Drainage (q. v.) and Irrigation (q. v.). The fertility and chemical composition of a soil may be approximately determined by inspection of its colour and texture; but more accurately, as well as its dryness or moisture, excess or defect of silica and alumina, by the predominance of certain species of wild plants or weeds.

SOISSO'NS, a town of France, in the dep. of Aisne, stands in a fertile vale on the banks of the river Aisne, about 65 miles north-east of Paris. S. is the key of Paris for an army invading France from the Netherlands, and is the meeting point of six military roads. The principal building is the cathedral, founded in the 12th c., the library of which contains many rare MSS. There are also some remains of the great castellated abbey of St Jean des Vignes, where Thomas à Becket found refuge when in exile. Quite near to S. is an institute for 'deaf and dumb,' which occupies the site of the famous abbey of St Médard, where Clothaire and Siegbert were buried. S. has manufactures of linen, woollens, and cottons. Pop. (1862) 10,208. S. is one of the oldest towns in France, and was celebrated even in the time of the Romans, when it bore the names first of *Noviodunum*, and afterwards of *Augusta Suessionum;* hence its modern name of Soissons. It was the last Roman stronghold in Gaul that withstood the arms of Clovis, who here overthrew Syagrius, the Roman commander, in 486, and made it the seat of the Frankish monarchy, which it long continued to be.

SÓKOTO, a kingdom of Africa, in Sudan, to the south-west of Lake Tchad, and separated from it by the state of Bornu (q. v.). Area, 117,180 sq. miles. The inhabitants, who are mostly of the Fulbe tribe, are numerous. A formidable military force is maintained.—*Sókoto*, the capital, stands on the Zirmie, an affluent of the Sókoto, which flows into the Quorra. Its market is of great importance; it trades in raw silk, glass-wares, and perfumery, carries on extensive and famous manufactures of leather goods, and has from 20,000 to 22,000 inhabitants.

SOLANACEÆ, or SOLANEÆ, a natural order of exogenous plants, mostly herbaceous plants and shrubs, but including a few tropical trees. The leaves are mostly alternate, undivided, or lobed, without stipules. The flowers are regular, or nearly so; the calyx and corolla generally 5-cleft; the stamens generally five. The fruit is either a capsule or a berry, mostly 2-celled. The plants of this order are mostly natives of tropical countries, a small number extending into the temperate and moderately cold climates of both hemispheres; in the coldest regions they are entirely awanting. They are mostly distinguished by an offensive smell, and by containing in greater or less abundance a narcotic, poisonous substance, usually associated with a pungent principle, and some of them are amongst the most active poisons. Sometimes the narcotic substance predominates, as in Mandrake (q. v.) and Henbane (q. v.); sometimes the pungent substance predominates, or is alone present, as in Cayenne Pepper (*Capsicum*); sometimes both are present in more or less equal proportion,

as in Tobacco, Thorn-apple or Stramonium, and Belladonna. The fruit is generally poisonous; but that of a considerable number of species, in which acids and mucilage predominate, is eatable, as, for example, the berries of the Winter Cherry and other species of Physalis, those of the Egg-plant (q. v.) and some other species of *Solanum*, and of the Tomato (*Lycopersicum*). The tubers, which occur in a few species, contain much starch, and serve as an article of food, of which the Potato is the chief example. The seeds of all contain a fixed oil, which in the south of Germany is expressed from the seeds of the Belladonna itself.

SOLAN GOOSE. See GANNET.

SOLA'NO. See SIMOOM.

SOLA'NUM, a genus of plants of the natural order *Solanaceæ*, containing a great number of species, which are distributed all over the world, but are particularly abundant in South America and the West Indies. Some of the species are herbaceous, others are shrubs; some of them unarmed, and some of them spiny; many covered with a down of starlike hairs. The flowers are in false umbels, or almost in panicles; seldom in racemes, or solitary. The anthers open by two holes at the top. The berries are two-celled, and contain many smooth seeds. The species of this genus almost always contain in all their parts a poisonous alkaloid, *Solanine*, in greater or less quantity, sometimes so much that the leaves or the berries cannot be eaten without danger, whilst in a few species the quantity present is so small as to be insignificant, and these parts are eaten freely, being agreeable and harmless. By far the most important of all the species is *S. tuberosum*, the POTATO (q. v.), in which, however, Solanine is found in considerable quantity, so that not only the herbage, but the juice of the raw tubers, is unwholesome. Of the species with eatable fruit, the principal is *S. melongena*, the EGG-PLANT (q. v.). —The only British species are *S. dulcamara*, the BITTERSWEET (q. v.), and *S. nigrum*, the COMMON NIGHTSHADE (q. v.), both of which possess poisonous and medicinal qualities. The berries, leaves, bark, and roots of various species are employed for different medicinal uses in the warm countries of which they are natives; but their properties have not yet been sufficiently investigated. The berries of *S. saponaceum* are used as a substitute for soap.

SOLAR, an upper chamber or loft. The only private apartment in the old baronial halls was so called. It was placed over the pantry, at one end of the hall, and served as parlour and sleeping apartment for the baron and his family.

SOLAR CYCLE. See PERIOD.

SOLAR MICROSCOPE, an instrument for producing magnified images of minute objects on a screen, through the agency of the sun's rays. The tube of the microscope is conical, and is fastened to the interior side of a closed window-shutter over a hole in the latter; a reflector, placed at the hole so that the rays of light may fall on it, is so adjusted as to throw them along the tube. They are then collected by a powerful double convex lens, and thrown on the object, which is inserted into the tube at the focus of the lens by a slit at the side. After passing the object, the rays again pass through a single lens, or a combination of lenses, make their exit from the tube, and fall on a screen, on which they depict a magnified image of the object. We have here supposed the object to be so translucent as to allow of the passage of rays through it. Should it be opaque, the rays of light reflected from the mirror are caught by the double convex lens, which concentrates them on another mirror near the opposite end of the tube; they are thence reflected upon the back of the object, and diverge on the system of lenses at the mouth, which form the image. Instead of the sun's rays, the oxy-hydrogen lime-light (and more recently the electric light) has been employed, its rays being thrown on the double-convex condenser by means of a concave reflector, in whose focus the piece of burning lime or marble is situated. The instrument is hence often called the *Oxyhydrogen Microscope*.

SOLAR SYSTEM. The planets and comets which circle round the sun combine with it to form a system to which is given the name of *solar* or *planetary* system. It is probable that each star is the centre of an analogous system. This, however, is merely a matter of speculation, and in no way practically concerns us; but it is different with the solar system. No change of much magnitude can take place in the elements of the planets without having effect on the earth and its inhabitants, on account of the mutual attractions of the planets for each other; in fact, they appear as members of one isolated family, bound together by common ties, which could not be ruptured in the case of one individual without communicating a general shock to the others. The various members of the solar system are noticed under PLANETS, PLANETOIDS, COMET, SUN, MOON, SATELLITES; and their motions are treated of under GRAVITATION, CENTRAL FORCES, PRECESSION, &c., so that it only remains here to give the more interesting numerical facts connected with them, which can be done most conveniently in a tabular form.

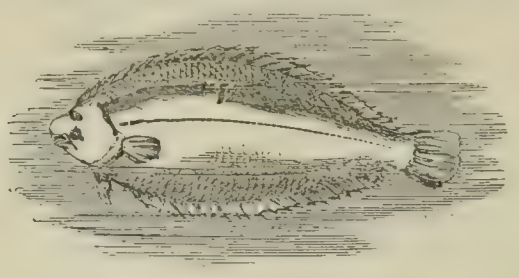
* Recent investigations make the sun's distance 91,600,000; and the sun's diameter, the planetary distances, &c., will therefore require a proportionate reduction.



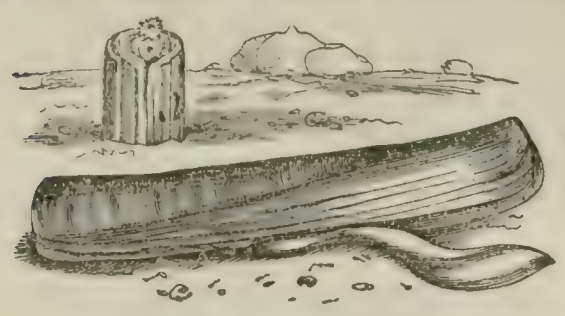
SOLA'TIUM, in Scotch Law, means compensation for wounded feelings, and is something over and above the ordinary pecuniary value of the damage. In England, such a ground of damages is not in strict principle admitted, but in practice there is no substantial difference.

SOLDER, an easily fusible alloy used for joining metals. Solders are of various kinds, suited to different metals. They always require to be used with a flux, such as borax, resin, chloride of zinc, sal-ammoniac, &c. The following are the principal solders: *Pewterers' solder*—bismuth, 2 parts; lead, 4 parts; tin, 3 parts. This can be used for coarse work by the direct application of naked fire; but for fine work, requiring the protection of a muffle-furnace, the composition must be bismuth and lead, of each one part; tin, 2 parts. *Plumbers' solder* for coarse work—tin, 1 part; lead, 3 parts. For finer work—tin, 2 parts; lead, 1 part. *Spelter solder*—12 parts zinc to 16 parts of copper. *Soft spelter solder*—equal parts of copper and zinc. When solders are applied in the common work of plumbers and tinmen, a tool called the soldering-iron is used: this is made red-hot, and forms a convenient means of applying fire direct to the solder and flux. Although called the soldering-iron, the portion of the tool to be heated must be of copper. In many manufactures, a flame produced by a mixture of atmospheric air and coal gas is used to melt the solder; and for fine work, such as jewellery, the common blowpipe is often used.

SOLDIER is one who enters into an obligation to some chieftain or government to devote for a specified period his whole energies, and even if necessary his life itself, to the furtherance of the policy of that chief or government. The considerà-tion may be immediate pay, or prospective reward: or the contract may be merely an act of loyal devotion. The acknowledgment of the service by the employer constitutes the man a recognised soldier, and empowers him to take life in open warfare, without being liable to the penalties of an assassin and a robber. The fact of being mercenary, that is, of receiving wages for killing and being killed, does not render a soldier's trade less honourable. He bears arms that others may be able to do without them: he is precluded by the exigences of military training from maintaining himself by peaceful occupation; and it is therefore but fair that those whom he protects should support him, and give him, over and above actual maintenance, reasonable wages for the continual risk of his life. If a man willingly enlist himself as a soldier in what he believes to be an unrighteous cause, it is an act of moral turpitude; but when once enlisted, the soldier ceases to be morally responsible for the justice or iniquity of the war he wages; that rests with his employer. Obedience, implicit and entire, is his sole virtue. The maxim is: 'The military force never deliberates, but always obeys.' See ENLISTMENT, MARTIAL LAW, WAR, &c.

SOLDO. See SOLIDUS.

SOLE (*Solea*), a genus of Flat-fishes (*Pleuronectidæ*), of an oblong form, with a rounded muzzle, which almost always advances beyond the mouth; the mouth twisted to the side opposite to that on which the eyes are situated, which is usually the right side, although individuals of the same species are found having the eyes and colour on the left side; the teeth very small, in both jaws, but only in the under part of the mouth (the *side* opposite to the eyes); the lateral line straight; pectoral fins on both sides; the dorsal and anal fins long, and extending to the tail, but distinct from the tail-fin. —The COMMON S. (*S. vulgaris*) is a highly esteemed fish, abundant on the British coasts where the bottom is sandy, and of which great quantities are brought to market. The London market is supplied chiefly from the south coast of England, the soles there attaining a larger size than those of more northern coasts. They are caught by trawling, very seldom with bait. The S. is in condition for the table during the whole year except five or six weeks in February and March, its spawning-time. The Common S. is found on all the coasts of Europe, except the most northern. It has been known to attain a size of 26 inches long, and almost 12 inches broad, weighing 9 pounds; but a S. of less than half that weight is reckoned very large. The upper



Common Sole (*Solea vulgaris*).

side of the body is of an almost uniform dark brown; the scales small, rough to the touch, and ciliated at the edge; the lower side is white. The S. sometimes ascends rivers to a considerable distance from the sea, and seems to thrive at least as well in fresh as in salt water, a fact of which advantage has not yet been taken for the stocking of fresh-water ponds. It breeds freely enough in fresh water.—The only other British species of true S. is the LEMON S. (*S. pegusa*), which is sometimes taken with the Common S. on the south coast of England, and more rarely in more northern parts. It is paler in colour than the Common S., and broader and thicker in proportion. It is equally esteemed for the table.—The name S. is popularly extended to several genera recently separated from the true soles. In *Brachirus*, the dorsal and anal fins are united with the tail fin; but, as in *Solea*, there are pectorals on both sides. To this genus belongs the ZEBRA S. (*B. zebrinus*) of Japan, remarkable for the zebra-like stripes which cross its whole body.—In *Monochirus*, the pectoral fin is developed only on the upper side. To this genus belong the VARIEGATED S. (*M. variegatus*) and the LITTLE S. or SOLENETTE (*M. linguatulus*), both found on the British coasts, but of little importance, on account of their small size.—In the genera *Achirus* and *Plagusia*, of which there are no British species, the pectorals are wanting on both sides.

SO'LECISM. A solecism is the term applied to any violation of the grammar or idiom of a language, or of the usages of society. It is said to be derived from the city of Soli in Cilicia, whose inhabitants spoke very bad Greek, in consequence of their intercourse with the Cilician natives, and provoked the fastidious Athenians to coin the epithet.

SO'LEN, a genus of lamellibranchiate molluscs, the type of a family, *Solenidæ*, remarkable for the wide gaping of the shell at both ends, and the large and muscular *foot*. In the genus S., the shell is remarkably elongated, its apparent length being, however, more strictly its breadth. From its form, the names RAZOR-SHELL and RAZOR-FISH are often given to it. The species are numerous, and inhabit the sands of all seas except in the coldest parts of the world. Some of the tropical species have shells of great beauty. The solens burrow in sand, making their hole straight down, and ascending and

descending by means of their foot, which is capable of being elongated and contracted to bore a passage for the animal, and to drag it through. They are used for food, and also by fishermen for bait. To obtain them, a hooked iron implement is used. Another

Solen, or Razor-fish (*S. siliqua*).

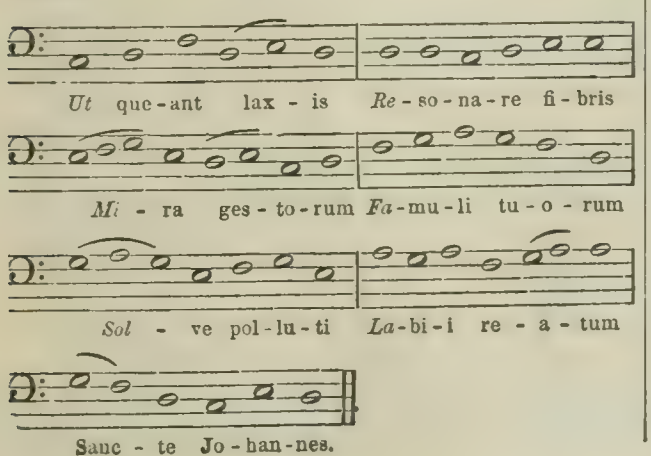
method is to drop a quantity of salt on the mouth of the hole, which causes them to come up, when they are quickly seized. The most common, and one of the largest British species, *S. siliqua*, is about an inch in *length*, and eight inches in breadth. It is perfectly straight. Another common British species, *S. ensis*, is curved like a sword.

SOLENHOFEN LITHOGRAPHIC STONE, a famous deposit of limestone of Upper Oolite age, which from its fine-grained and homogeneous texture is admirably adapted for lithographic purposes. It occurs near Aichstadt in Bavaria, and has been extensively quarried since the invention of lithography. The quarrymen work upon the lines of stratification, which are beautifully parallel, and all the fossils are found upon the natural surfaces of the beds, and present an impression and cast in

Remains of Archæopteryx in Solenhofen Stone.

almost every instance. The rock is quarried to a depth of 80 or 90 feet. It is of special interest to the geologist from the singular assemblage of fossil remains which are preserved in it with wonderful minuteness. The most delicate tracery of the wings of the dragon-fly is often as perfect as in living specimens. The rock is of marine origin, and while lithologically it has a strong resemblance to the White Lias of Britain, its fossils correlate it to the Kimmeridge Clay. These are chiefly ammonites, nautili, crustacea, winged insects, fishes, and pterodactyles. But the most singular fossil is one which has only recently been brought to light. A single feather was first found, and some months after, the bones of a feather-covered animal, which was considered by its first describers to be a lizard, but Professor Owen has recently shewn, on incontrovertible grounds, that it is a true though very anomalous bird. The specimen which, with the exception of the head, is almost entire, is now in the British Museum. It has formed the subject of an elaborate memoir by Professor Owen, published in the *Philosophical Transactions*. He has named it *Archæopteryx macrura*. It is certainly the oldest bird of which any remains have yet been found, but the rocks which contain the numerous ornithic footprints in Connecticut Valley (see ICHNOLOGY) are more ancient; the most careful examination has, however, hitherto failed to discover in them any indications other than the footprints. The *Archæopteryx* was about the size of a rook. The anomalous structure which induced the earlier observers to make it a reptile, and some that followed to imagine it as a transition form between the reptile and the bird, is the tail, which, instead of consisting of a few shortened vertebræ united together into a coccygean bone, as in all known birds, recent or fossil, was formed of twenty elongated vertebræ, each of which supported a pair of quill-feathers. But this departure from the bird type is not so anomalous as it at first sight appears, for in the early embryonic condition of the bird, the vertebræ are distinct and separate, and the anastomosis which invariably takes place in the subsequent development of the embryo, does not occur in the *Archæopteryx*, so that it may be considered to exhibit the temporary embryonic condition of the bird as a permanent structure; and that this is the true position of this singular fossil is further established by the existence of other features which are found only in birds. These are the ornithic structure of the wings and legs, the occurrence of feathers, which are confined to birds, and the existence of a merry-thought (furculum), which is found in no other class of animals. An elevation on the surface of the slab containing the fossil is believed by many to be the cast of the interior of the skull, and it corresponds remarkably in size and form with the cast from the skull of a rook.

SO'LENT, the name of the western portion of the strait that intervenes between the Isle of Wight and the mainland of England. At Hurst Castle, which guards its entrance on the south-west, the S. is less than a mile in breadth; and along this narrow passage the tide flows with a rapidity which at certain times no boat can stem. The castle itself consists of a central tower or keep, surrounded by several smaller towers, and mounted with heavy guns.



SOLEU'RE (Ger. *Solothurn*), a canton in the north of Switzerland, bounded on the W. and S. by Bern, and on the N. and E. by Basel and Aargau. Area, 288 sq. m.; pop. (1860) 69,263, mostly Roman Catholics. The greater portion of the canton is fertile and well cultivated, especially along the banks of the Aar. Even the rugged and hilly districts are sources of wealth on account of their fine pasturage. Besides grain, the principal products of S. are fruit, wine, flax, and cotton

Cherry-brandy is a very important article of trade. The manufacture of iron, glass, pottery, hosiery, and recently of watches, is carried on to a considerable extent.—S. entered the Swiss Confederation in 1481 along with Freiburg. Its constitution is liberal. The legislative body, or parliament, is the Grand Council, consisting of 105 members, of whom 55 are directly chosen by the people, 41 indirectly, and 9 by the Grand Council itself. The executive, or council of government, is under the presidency of a landamman.

SOLEURE (Ger. *Solothurn*), capital of the canton, is situated on the Aar, 16 miles north-north-east of Bern by railway. The scenery in its vicinity is among the loveliest in Switzerland, The Aar flows through the town, dividing it into two unequal parts, which are connected by two wooden bridges. The most notable building is the cathedral of St Ursinus, with a cupola and façade of Corinthian columns, reckoned the most costly cathedral in Switzerland. S. has some manufactures, but derives its chief industrial importance from its transit-trade. Pop. 5370.—Near to S. are the baths of Weissenstein.

SOLFATA'RA (Fr. *Soufrière*, Ger. *Schwefelgrube* or *Schwefelsee*), the Italian name for such volcanoes as, having become less active than volcanoes in an actual state of eruption, only exhale gases. The most notable of them are found in Italy, in the Antilles, in the interior of Asia, and in Java. The S. of Pozzuoli, near Naples, is an irregular plain, 1368 feet long, and 1310 feet broad, almost surrounded by broken hills of pumaceous tufa, the ancient walls of the crater. From the crevices of the rocks, steam or noxious gases, chiefly sulphuretted hydrogen, mixed with a minute quantity of muriatic acid and muriate of ammonia, exhale. In the cracks and fissures of the rocks, sulphur, alum, and sulphate of iron abound. The vapours exhaled are used as medicinal baths, and huts, constructed of boards, have been erected in which the baths may be obtained. The Soufrière of Morne-Garou, in the isle of St Vincent, Lesser Antilles, about three miles in circuit, and over 500 feet in depth, has in its centre a cone, the summit of which is covered with sulphur.

SOLFE'GGIO, in Music, seven syllables, which are sometimes used as a nomenclature for the seven notes of the scale. In singing, the art of applying these syllables to the notes as an exercise for the learner, is called *Solmisation*. The syllables are *ut* (or *do*), *re*, *mi*, *fa*, *sol*, *la*, and *si*. The first six are the commencement of the lines of an ancient monkish hymn to John the Baptist, which had this peculiarity, that the first syllable of each line was sung to a note one degree higher than the first syllable of the line that preceded, so as to present the type of a scale:

These syllables are said to have been first made use of by Guido of Arezzo, in the 11th c.; and Le Maire, a French musician of the 17th c., added to them *si*, for the seventh of the scale. When applied to the key of C, their equivalents, in the ordinary musical nomenclature, are:

Do	re	mi	fa	sol	la	si	do
C	D	E	F	G	A	B	C.

These syllables may, however, according to the more modern practice of teachers in this country, be applied to other keys, with *do* always as the keynote, so as to express not the absolute pitch of a note, but its relation to the keynote; and thus used, they are thought to be of service to the learner in keeping prominently before him the principle that there is but one scale in music, which is raised or lowered according to the pitch of the key. Different variations in the way of using the syllables have recently given rise to various supposed short and easy modes of teaching singing, the best-known of which is Mr Curwen's system of 'Tonic Solmisation,' where the ordinary notation of the staff, with its lines and spaces, is entirely rejected, and a notation substituted which is formed of the solfeggio syllables, used to express not pitch but relation to the keynote. One disadvantage of this and similar schemes is the entire withdrawal of the direct indication of the pitch of the sounds to the eye, by the notes ascending as the sounds ascend, which is so beautiful a feature of the common notation. And even if it be granted that the first rudiments of music can, as has been asserted, be taken up with remarkable ease by the pupil who learns on the tonic sol-fa system, it is undeniable that as soon as he comes in contact with notes of different lengths, or begins to modulate from one key to another, he is beset with serious difficulties. There is, in addition, the further objection to the system, that the pupil thus taught is shut out from the whole world of musical literature, a disadvantage which is not compensated by having a few elementary difficulties smoothed away, which experience shews that children of the most mediocre capacity can overcome.

SOLFERI'NO, a village of Northern Italy, province of Brescia, 20 miles north-west of Mantua, with 1400 inhabitants. It stands on a hill, and has a tower called the Spy of Italy (*Spia d'Italia*), from which the whole plain of Lombardy may be seen. There, in 1796, the French conquered the Austrians. On June 24, 1859, S. was again the scene of an overwhelming victory obtained by the French and Italians over the Austrians.

SOLICITOR. See ATTORNEYS.

SOLICITOR-GENERAL, the name given to one of the law-officers of the British crown. The Solicitor-general of England has powers similar to those of the Attorney-general (q. v.), to whom he gives aid in discharging his functions. During the absence of the Attorney-general, he may do every act and execute every authority of that officer. He is, *ex officio*, one of the Commissioners of Patents.

The Solicitor-general of Scotland is one of the crown counsel, next in dignity to the Lord Advocate (see ADVOCATE, LORD), and exercising all his functions along with him. His office cannot be traced further back than the Union. Like the Lord Advocate, he has the privilege of pleading within the bar. All proclamations for the observance of days of public fasting and thanksgiving are addressed to the Solicitor-general.

SOLICITOR TO THE TREASURY, an officer who acts as attorney for the British government in all legal proceedings. He has also to act as solicitor for

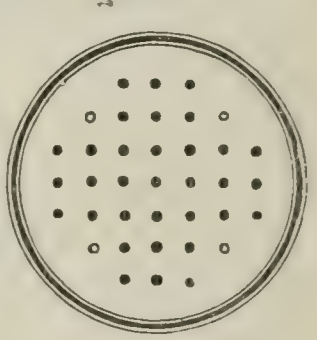
the three secretaries of state, the Privy Council Office, the Board of Trade, the Mint, the War Office, the Stationery Office, and for all the other principal departments for which no solicitor is specially appointed.

SOLIDUNGULA. See EQUIDÆ.

SOLIDUS, the name by which the old Roman aureus' (equivalent to £1, 1*s.* 1½*d.*, according to the present value of gold) was known after the time of Alexander Severus; but during the reign of Constantine the Great, its value was diminished in the ratio of 8 : 5, and so remained till the end of the empire. The weight of these later solidi was fixed at $\frac{1}{6}$th of an ounce, the gold being 23 carats fine, and the alloy mostly native silver. The 'solidus,' or 'solidus aureus,' was adopted by the Franks under the Merovingians and Carlovingians (at 87 to the Roman pound) till the time of Pepin, who suppressed it; but another solidus of silver, or 'solidus argenteus'—the $\frac{1}{20}$th of the libra or pound—which had been used only as a money of account, was soon after made a coin. In after-times, this 'sol,' or 'sou,' like all other coins, underwent an infinity of variations in fineness and value (see LIVRE). On the introduction of the decimal system (1793) into France, the sou was abolished, and a piece of 5 centimes ($\frac{1}{20}$th of a franc) substituted, but the name continued in common use, and the old sous were retained in circulation. The solidus also appears in the *soldo*, which was a coin in use in Northern and Central Italy, and was essentially the same with the sou.

SO'LINGEN, a town of Prussia, province of the Rhine, and government of Düsseldorf, capital of a circle of the same name, is situated on a height 13 miles east-south-east of Düsseldorf, and not far from the river Wupper. It is a very old place, and has long been famous for its steel and iron ware manufactures, especially sword-blades, helmets, cuirasses, knives, scissors, which are exported to all parts of the world, and rival the excellence of English wares. In 1857, the town and circle of S. employed 8048 workmen, who produced from 400,000 to 500,000 sword-blades yearly, from 1,500,000 to 2,000,000 dozen knives, and nearly 1,000,000 pair of scissors. The total value of the steel-wares amounted to about 5,000,000 thalers. Pop. 12,989.

SOLITAIRE (*Pezophaps*), a genus of birds of the Dodo (q. v.) family (*Didinæ*), but differing from the dodos in a smaller bill and longer legs. Like the dodos, the only species of this genus, of the existence of which there is any evidence (*P. solitaria*), seems to be now extinct, and to have become extinct in very recent times. It inhabited the island of Rodriguez, an island about 15 miles long by 6 broad, situated about 300 miles to the east of Mauritius, and appears to have been peculiar to that small and lonely island, where it was abundant at the beginning of the 18th century. Rodriguez was uninhabited till 1691, when a colony of French Protestant refugees settled on it, under the command of François Leguat, who, in his *Voyages et Aventures*, has left an interesting and trustworthy account of the solitaire. He describes it as a large bird, the males sometimes weighing 45 lbs.; taller than a turkey, the neck a little longer in proportion, and carried erect; the head of the male without comb or crest, that of the female with something like a widow's peak above the bill; the wings small, and the bird incapable of flying, but only using the wings to flap itself or to flutter when calling for its mate, or as a weapon of offence or defence; the bone of the wing being thickened at the extremity so as to form a round mass, about the size of a musket-bullet, under the feathers, and to increase the force of the blow given by it; a roundish mass of feathers instead of a tail. He further describes the plumage as very full and beautiful, not a feather out of its place, so there can have been no feathers with unconnected webs, as in the ostrich. He says the bird is called S. because it is very seldom seen in flocks. He tells us that the bird is with difficulty caught in the forests, but easily on open ground, because it can be outrun by a man; and that its flesh is very good to eat.—But the S. seems to have completely disappeared from Rodriguez, which is now a British settlement. Bones have been found, although not yet abundantly, and some are preserved in the Paris Museum, some in the Andersonian Museum, Glasgow.



Solitaire (*Pezophaps solitaria*).

The figure here given is derived from a rude cut in Leguat's work, and its general accuracy is attested by its correspondence with small figures introduced in a landscape and two maps in that work.

The name S. was originally given to a species of dodo inhabiting Bourbon, and applied by Leguat to this bird, in a mistaken belief of its being the same. See *Strickland and Melville on the Dodo and its Kindred.*

SOLITAIRE, a species of game or rather puzzle, which, as the name denotes, is played by only one person. The apparatus for the game consists of a round or octagonal flat board, indented with 33 or 37 hemispherical hollows, as in the figure, and 33 or 37 balls, one in each hollow. The process of the game consists in removing one ball from the board, and then, having created a vacancy, capturing one of the balls adjoining by causing the one behind to leap over it into the vacant hollow; there are now two vacancies, and the game is continued in the same manner by capturing ball after ball, till only one remains, when the game is *won.* Should more than one be left, and they be so isolated as not to be liable to capture by each other, the game is *lost.* This puzzle may be solved in an immense number of ways; one of the prettiest modes consists in removing the central ball, and so capturing the others that the last ball shall be in the centre.

Solitaire.

SOLLE'R, a small town and seaport of the Balearic Isles, in Majorca, 14 miles north of Palma. It exports oranges and wine, and contains 7000 inhabitants.

SOLMISATION. See SOLFEGGIO.

SOLO, a term used in musical compositions of several parts, whether vocal or instrumental, to indicate those voices or instruments that are to perform alone or in a more prominent manner, as

soprano solo, *violino solo*. The plural, *soli*, is used when two or more voices or instrumental parts are to be performed together, such parts, of course, never being doubled.—A composition for a single instrument accompanied is also termed a solo.

SOLO'FRA, a city of Italy, province of Principato Ulteriore. Pop. 3504. It is situated on the Apennines, and is surrounded by wooded mountains.

SO'LOMON (Hebr. Shĕlômô, Salomon, Salomo, Suleimân, derived from *shalom*, peace = Peaceful, like Germ. Friedrich), the second son of David and Bathsheba; successor of the former on the throne of the Israelitish empire for forty years (1015—975 B.C.*). Nothing is known of his youth except that he was probably educated by Nathan (or Jehiel). Equally uncertain is the age at which he succeeded to the crown of his father. That he was older than twelve or fourteen years, as some traditions tell us, seems certain. The way in which his succession to the throne during the lifetime of his father was brought about, to the exclusion of his elder brother Adonijah, is not undeserving of the name of *coup d'état*, which has been bestowed upon it (see the Scripture narrative). Having, by the execution of Adonijah and the leaders of his faction, secured his dominion against internal foes, he, with complete disregard of the Mosaic law, set himself to seek foreign alliances, and with this view married as his principal wife the daughter of Pharaoh, probably of Psusenes (Vaphres?), of the twenty-first dynasty. Besides her, however, he had a vast number of wives—700 'princesses,' and 300 'concubines'—the greatest part of whom were recruited from nations with whom an alliance had been strictly prohibited. Having inherited fabulous wealth, and further adding to it enormously from his own multifarious revenues, so that 'silver was nothing accounted of in his days,' it became necessary that a new organisation corresponding to this unheard-of splendour should be introduced. Accordingly, we hear of 'Princes,' i. e., great officers of state, not before heard of. The two counsellors of David's time disappear, in order probably to make room for a whole body of legal advisers; the prophets are no longer to be found among the dignitaries of state, but new military charges are created instead. The immense accumulation of treasure also allowed the execution of a number of public works in Jerusalem, which now first assumed the magnificence and station of a capital. A new wall with fortified towers was erected around it; and the Queen's Palace—'the House of the Forest of Lebanon'—with a long hall joined to it by a cedar porch, called the 'Tower of David,' outside of which a thousand golden shields were suspended, and within which the king sat, in all his imperial splendour, to pass judgment, were built under his immediate orders. His banquets, at which all the vessels were of gold; his stables, with their four (or forty) thousand stalls; his gardens and parks and summer retreats, were such as to dazzle even eastern fancy. Twelve commissaries, distributed in the different provinces, had each in his turn to furnish the means of sustaining this prodigious household. The dominion of S. extended from Thapsacus, on the Euphrates, to Gaza, on the Mediterranean. The country was in the profoundest state of peace; the treasures accumulated by David appeared inexhaustible; and the popularity of the king, who listened to the meanest of his subjects, and gave judgment according to that wisdom, for which he had asked in his vision at Gibeon, in preference to any other gift, and which has remained proverbial from his day to ours, was naturally at first very great. Everything, moreover, was done to develop and increase the national wealth and welfare. The rich internal resources were developed, and commercial relations of the most extensive nature established.

Through the port established at Ezion-Geber, at the head of the Gulf of Elath, an outlet was gained to the Indian Ocean; and the alliance with Phœnicia, then under the sway of Hiram, gave an energetic impulse to these foreign expeditions. Manned with Tyrian sailors, the Israelite fleets went to 'Ophir,' and brought back, in exchange for their own exportations, 'gold and silver, apes and peacocks, ivory and spices;' and the rest of the strange and precious produce of India, Africa, Spain, and other regions, possibly even the British coasts.

According to his promise, S., in the fourth year of his accession, commenced the building of the Temple on Moriah, after the model of the Tabernacle, wherein he was aided by Hiram, who not only sent him timber, but architects and cunning Phœnician artists in wood and stone and metals. In the eleventh year of his reign it was completed, and solemnly inaugurated in the following year—at which occasion prodigious numbers of sacrifices were slaughtered. Thirteen years more having been spent in the construction of the 'House of the Forest of Lebanon' (the royal palace), other buildings and fortifications—among them that of Palmyra—are recorded to have been undertaken by the king, who, far from wishing further to extend his dominions, was only bent upon keeping his frontiers safe from the raids of the neighbouring hordes, and for that purpose alone kept up an unprecedentedly large army.

The fame of S. could not but spread far and near. The splendour of his court and reign, heightened by his personal qualities, his wisdom and erudition—for he was not only the wisest but also the most learned of men—brought embassies from all parts to Jerusalem to witness his magnificence, and to lay gifts of tribute at his feet. The queen of Sheba's expedition and presents are well known; and as many Arab kings made him annual presents of a no less splendid nature, his income from different sources was calculated, in round numbers, at the enormous sum of 666 golden talents. That people of Moses, which was to know no other wealth than flocks and the fruits of the soil, had suddenly become a people of wealthy merchants, of soldiers, and of courtiers—and it did not profit by the change, chiefly through the bad influence of the king himself and his court. The army and the public buildings absorbed the resources of the provinces. In the Temple, erected for the purpose of the true worship of Jehovah, S. sacrificed three times a year; but nevertheless, to please his concubines, he allowed, and perhaps himself indulged in, the rites of polytheism on the heights, thereby setting the worst example to his subjects, sufficiently eager already to worship foreign deities. His exaggerated polygamy fostered immorality and licentiousness among the people; and, worst of all, the wise and gentle monarch, as his treasure got exhausted, began, toward the end of his reign, to lay the yoke, which hitherto had lain only on his Canaanite subjects, upon the Israelites themselves. And he thus became, to all intents and purposes, an eastern despot—selling part of his dominion to raise money, and trying to break the spirit of the nation by forced services and corporal chastisements.

Left by the 'prophets,' probably since his open and revolting infidelity with regard to the national worship, his advisers were chiefly insolent young

*There is some discrepancy among investigators about this date; the beginning of his reign being fixed variously at 1009, 1025, 990, &c.

courtiers, who awed even his aged counsellors into silence, and from that time forth a storm began to gather over the land. The priests were on the side of the malcontents, and a vague talk of a general rising, which actually found utterance by a 'prophet' in the face of S., was heard throughout the country. Ahijah of Shiloh predicted, as Samuel had done to David, the partial dominion to the Ephraimite Jeroboam, who had to flee for his life to Egypt. But notwithstanding these internal mutterings, and the open revolts of one or two subject chiefs, such was the prestige both of David's and S.'s name, that the king was allowed to die in peace.

S. is supposed to be the author of Canticles (q. v.), Ecclesiastes (q. v.), Proverbs (q. v.), besides works on Science which are said to be lost. But he is also to be considered the prime cause of the final and decisive downfall of the Jewish commonwealth for all historical times. His wisdom turned into folly, his justice into tyranny, raised a smouldering discontent which only awaited his death to break out into open flames of revolt and internal wars. His character presents the lamentable spectacle of genius gone astray; and many have been the discussions on the part of learned theologians in old and late times as to whether or not there was any hope of his 'salvation.' His name and his glory, however, will, notwithstanding the shadows that fall over his latter days, remain immortal, whether we look at the striking picture of him given in Scripture, or to the more gorgeous kaleidoscope of Eastern legends revolving round the golden name of Suleiman: the Lord and Master of all animate and inanimate beings under the sun, the most beautiful, the most wealthy of all created men, and whose wisdom was as much without limits as were his riches and power.—See for such legendary accounts of S., Weil's *Biblical Legends*, the *Targums*, the *Koran*, Lane's *Arabian Nights*, D'Herbelot, Ginsburg, Fürst's *Perlenschnüre Suleiman-Nameh*, in 70 books, ascribed to a Turkish poet, Firdusi, &c.

SOLOMON ISLANDS, a chain of islands in the Malay or Indian Archipelago, between New Britain on the north-west and the Queen Charlotte Islands on the south-east; lat. 4° 50′—11° 50′ S. Area estimated at 10,000 sq. m.; pop. thought to be considerable, but not ascertained. The natives are partly Negrilloes, partly Malays, and are still in the condition of savages.

SOLOMON'S SEAL (*Polygonatum*), a genus of plants of the natural order *Liliaceæ*, differing from Lily of the Valley (q. v.) chiefly in the cylindrical tubular perianth, and in having the flowers jointed to their flower-stalks. There are three British species. The English S. S. (*P. multiflorum*) is found in woods and copses in many parts of England, and in a few places in Scotland. It has a stem about two feet high, the upper part of which bears a number of large, ovate-elliptical, alternate leaves in two rows. The flower-stalks are generally branched; the flowers not large, white, and drooping.—The NARROW-LEAVED S. S. (*P. verticillatum*) is a rare British plant, only found in a few places in Scotland. The leaves are whorled.—The ANGULAR, or SWEET-SMELLING S. S. (*P. officinale*) is also rare in Britain, and is found only in England. It more nearly resembles the Common S. S., but is smaller, and has greenish, fragrant flowers. All these species are common in many parts of Europe. They are very similar in their properties. The young shoots of *P. officinale* are eaten by the Turks like asparagus. The root is white, fleshy, inodorous, with a sweetish, mucilaginous, acrid taste. It contains *Asparagin*. It is a popular application to bruises, to prevent or remove discoloration, and its use is well known to those who are too apt to get a black eye now and then.

Solomon's Seal (*Polygonatum multiflorum*).

P. biflorum, *giganteum*, and *latifolium* are common in woodlands in the northern United States.

SO'LON, the most famous of all the ancient Greek lawgivers, was a native of Athens (born about 638 B. C.), and belonged to one of the most distinguished families of Attica. His father, Execestides, having seriously impaired his income by improvidence, S. was obliged, while still young, to embark in trade. At first, however, S. comes before us as an amatory poet. His earliest appearance in the field of politics was occasioned by the contest between Athens and Megara for the possession of Salamis. By force of artifice, S. revived the martial spirit of his countrymen, which had sunk under the effect of repeated disasters, obtained command of a body of volunteers, and conquered the island (*circa* 596 B. C.), in which, along with others, he obtained a grant of land. Henceforth his public career is conspicuously noble and honourable. He figures as a wise and unselfish patriot, seeking earnestly, and not in vain, to compose the distractions, partly social and partly political, that rent his native city. The Athenians generally had thorough confidence in his integrity; and in 594 B.C. he was chosen archon or chief magistrate, and received unlimited permission to act as he saw best for the good of the state. In short, to borrow a phrase from Roman history, he was invested with dictatorial power. The nature and extent of the Solonian legislation has been the subject of much criticism in modern times, and Mr Grote, in particular, has made it very clear that the 'later ancients' (Plutarch and Diogenes Laërtius), on whom we are obliged to rely for almost all our information about S., are full of confusions, misapprehensions, and contradictions, and that it became a habit among them to mythically attribute to the great Athenian every bit of wise legislation whose paternity they could not discover.

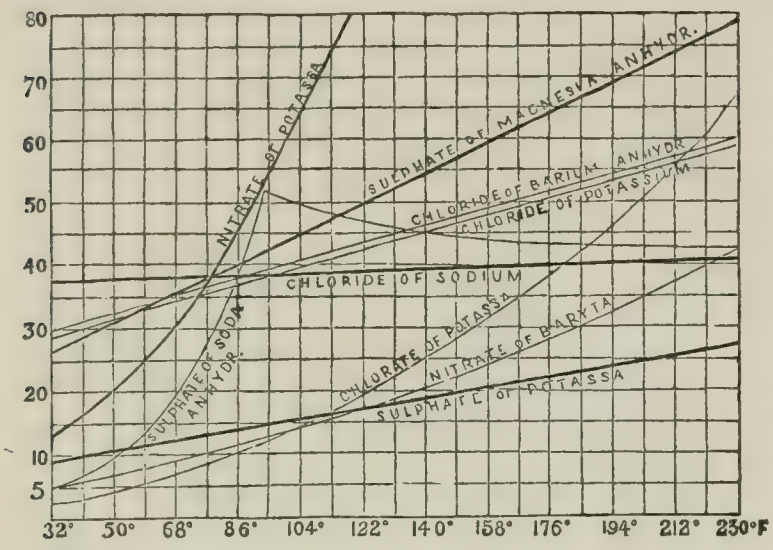
In order to alleviate the wretchedness arising from the existing relations of debtor and creditor, which was no longer supportable, and was likely to create a social war, S. proposed and carried a notable measure—the *seisachtheia*, or 'disburdening ordinance' (from *seio*, to 'shake off,' and *achthos*, a 'burden')—which received its name from its design—viz., to lighten the burden of debt that weighed down the *Thetes*, or lower classes. How this was effected, is far from being correctly explained

by Plutarch, and the reader who wishes to have the most rational solution of the matter must consult Grote's *History of Greece* (vol. iii.). From redressing the grievances of a class, S. proceeded, at the solicitations of his countrymen, to remodel the constitution; and here, too, the qualities that are popularly associated with his name shine out conspicuously. Abandoning the semi-civilised theory which regards the nobles as alone worthy of citizenship, and of the honours of public office in the state, he introduced the timocratic, or rather the plutocratic principle—classifying citizens according to their wealth or property; the effect of which was not to wrest *all* power or dignity from the hands of the *Eupatridæ*, or well-born class, but only to give a portion of it to others who might be as wealthy, and therefore, presumably, as intelligent and cultivated as they. Such a reform has been compared to that previously effected by Servius Tullius in the constitution of ancient Rome; and there is at least a striking resemblance in the method, if not in the design, of the two reforms. See ROME. S. distributed the citizens into four classes. The first embraced all those whose yearly income reached 500 medimni; the second, those of between 300 and 500 medimni; the third, those of between 300 and 200 medimni, and the fourth, those whose income fell below 200 medimni. The first three classes were liable to *direct* taxation; the fourth not; but all were liable to *indirect* taxation. With regard to the *Boule*, or Deliberative Assembly of Four Hundred, it would seem that S. left it the strictly aristocratical body that he found it. Its power, however, was practically limited by a new *ecclesia*, or assembly of the four classes, whose ratification was necessary to all measures originating in the *Boule*, or 'Upper House.' On the other hand, the *ecclesia* itself could originate nothing, and thus the Attic aristocracy and the Attic plebs could mutually check each other's assumptions. The part of S.'s legislation relating to the industrial pursuits of the citizens appears to have been as excellent and well considered as the rest, but the number of his special enactments is so great that we cannot afford space to mention them. It is enough to state that they embraced almost every subject of social importance; and the best testimony to their value lies in the fact, that when Peisistratos violently overthrew the political constitution established by his kinsman, he allowed his social legislation to stand. See PEISISTRATOS.

The story of S.'s leaving Athens for ten years, after he had completed his labours as a lawgiver, and travelling into foreign countries, may be, and probably is historical, but the details are untrustworthy; and in particular, the celebrated incident of his interview with Crœsus will not suit the requirements of chronology, and must be relegated to the domain of historic myths. During his absence, the old dissensions among the Athenians broke out, and when he returned, S. struggled in vain to repress them. A strong hand, as well as a wise head, was needed, and the conspiracy of Peisistratos was quite as much one against anarchy as against the constitution. After S.'s defeat, he withdrew into private life, but occasionally assisted with his advice his bold, ambitious, and able kinsman, who had so effectively crushed the Athenian 'disorderlies' of all parties. The date of his death is uncertain.

SOLO'R ISLANDS, THE, lie east of Flores, between 122° 56′ 30″—124° 25′ E. long., and belong to the Netherlands Residency of Timor. Besides several groups of smaller islands, they consist of Solor, with an area of 105 sq. m., and a pop. of 15,000; Adanara, 302 sq. m., pop. 36,000; Lomblem, 520 sq. m., pop. 120,000; and Pantar, 275 sq. m., with 60,000 inhabitants. Solor and Adanara are separated from Flores by narrow straits, Lomblem and Pantar lie in succession further east.

Solor has little cultivated land, the natives being good sailors, and chiefly employed in fishing. Much sulphur and saltpetre are found, from which gunpowder is made. The women weave coarse fabrics for clothing, and exotic cotton has lately been planted with success. Edible nests are extensively collected. In all the villages on the coast, markets are statedly held, and numerously frequented. The natives near the sea are Malays, friendly to the Dutch, a few of them Christians, the others Mohammedans. Those of the interior are Alfoors, wild and warlike, who use shield and bow, sword and firearms. Adanara is governed by an independent rajah. It is a lovely island, having hills and dales, picturesque villages, and cultivated fields. The people are Malays, partly Mohammedans and partly Roman Catholics. Lomblem is also beautiful, the natives Malays; those of Pantar being Papuans.



The S. I. are mountainous; the volcano Lobetolle, in Lomblem, is 4914 feet high; and the mountains of Pantar, 3332. They are clothed to their summits with forests. In 1851, the Portuguese relinquished all claim to these islands, which are now governed by the military commander at Larantooka, in the east of Flores; a Dutch postholder being stationed at Lawajang, the chief place of Solor.

SO'LSTICE (Lat. *solstitium*, from *sol*, sun, and *sto*, I stand), that point in the ecliptic at which the sun is furthest removed from the equator, and where he is consequently at the turning-point of his apparent course. There are two such points in the ecliptic, one where it touches the tropic of Cancer, the other where it touches that of Capricorn. The former is the summer, and the latter is the winter solstice to those who inhabit northern latitudes, and *vice versâ*.—The term is also employed to signify the *time* at which the sun attains these two points in its orbit, viz., the 21st of June and the 22d December.

SOLT, a town of Hungary, county of Pesth-Solt, 48 miles south of Pesth, in a marshy district on a branch of the Danube. Pop. 4073.

SOLU'TION. A substance is said to undergo solution, or to become dissolved, when the force of adhesion between it and a liquid in which it is immersed is sufficient to overcome the force of cohesion between the solid particles. Thus sugar or salt is dissolved by water, camphor or resin by spirit of wine, and silver by mercury. The liquid which effects the solution is termed the *solvent*, or sometimes the *menstruum;* and some solutions have special names—for example, the term *syrup* is applied to a solution of sugar in water, and *tincture* to a solution of a solid in alcohol. If a solid body be introduced in successive small portions into a definite quantity of a liquid capable of dissolving it, the first portions disappear the most rapidly, and each successive portion dissolves more slowly than its predecessor, until a point is reached at which the liquid ceases to possess any further solvent power. When this occurs, the forces of cohesion and adhesion are balanced, and the liquid is said to be *saturated*. Solution is promoted by increasing the extent of surface in a solid, or by reducing it to powder. An elevation of temperature, by diminishing cohesion, will generally also increase the solvent power of the liquid; but there are exceptions to this rule—as, for instance, in the case of lime and its salts, water just above the freezing-point dissolving nearly twice as much lime as it does when boiling. A compound of lime and sugar, very soluble in cold water, is separated from the solution almost completely, if heated to boiling.

But the most remarkable case of the kind occurs in sulphate of sodium (Glauber's salt), which in its crystalline form dissolves in about ten times its weight of ice-cold water, and rapidly becomes more soluble as the temperature rises until it reaches 91°; from this point until the solution boils, the solubility slightly decreases, the boiling liquid retaining only about four-fifths of the quantity which was dissolved at 91°. Carbonate and seleniate of sodium, and sulphate of iron, exhibit the same peculiarity in a less marked degree. 'These anomalous results may be partly explained,' says Dr Miller, 'by the consideration that heat diminishes the force of adhesion as well as that of cohesion. Generally speaking, cohesion is the more rapidly diminished of the two, although not uniformly so; and in these cases it would appear that the adhesive force decreases in a greater ratio than the cohesion of the saline particles' (*Chemical Physics*, 3d ed. 1863, p. 72). The accompanying diagram shews the unequal solubility

of various of the more common salts in water of different temperatures. The *lines of solubility* cut the verticals raised from points indicating the temperature upon the lower horizontal line, at heights proportional to the quantities of salt dissolved by 100 parts of water. For example, 100 parts of water dissolve—at 32°, 8 parts, at 122°, 17 parts, and at 212°, 26 parts of sulphate of potash. Water which has been saturated with one substance, that is, which refuses to dissolve any more of that substance, will often continue to dissolve others. In true or simple solution, the properties both of the solid and the solvent are retained. When, however, any chemical action ensues between the solid and the liquid, the resulting solution commonly presents perfectly new and distinct features; as, for example, when the metals are dissolved by acids, or oils by the alkalies (as in soap-making). For the solubility of the gases in water, we must refer to the article Gases.

The uses of solution in laboratory processes are numerous. By the difference in degree of their solubility, we can separate one substance from another; and by dissolving a body we can purify it either by filtration or crystallisation. Moreover, when it is required that two bodies shall react on one another, they do so with incomparably more force in their dissolved than in their solid state.

SOLVENT. See Solution.

SOLWAY FIRTH—in its upper part best regarded as the estuary of the river Esk; in its lower, as an inlet of the Irish Sea—separates the north-west of Cumberland from the south of Scotland. Its entire length, until lost in the Irish Sea, is calculated at 33 miles; its average breadth for the first 12 of these is not more than 2½ miles, but afterwards it gradually, although irregularly, increases to upwards of 20. The principal rivers flowing into it, besides the Esk, are the Annan, Nith, Dee, and Urr, from the north or Scottish side; and the Eden and Derwent from the south or English side. The most striking feature of the S. F. is the rapidity with which its tides ebb and flow. The spring-tides are peculiarly swift and strong—the wave rushing in from 3 to 6 feet high, and at the rate of 8 to 10 miles an hour, occasionally inflicting serious damage on the shipping; while after it has retreated, great stretches of the bed of the firth are left bare, and in some places one can even cross over from the English to the Scottish shore. The salmon-fisheries of the Solway are valuable.—*Solway Moss* is a district of Cumberland about 7 miles in circumference, lying west of Longtown, and immediately adjoining Scotland. As its name implies, it was once a bog, but is now drained and cultivated. It is historically notable as the scene of a battle between the English and Scots in 1542, when the latter were defeated. Here also, on 13th November 1771, an extraordinary disaster occurred. The boggy ground, surcharged with moisture—the effect of heavy rains, rose, swelled, and burst like a torrent, sweeping along with it trees and houses, and destroying some 30 small villages.

SOLYMAN (SULEIMAN) II., surnamed 'The Magnificent,' the greatest of the Turkish sultans, was born in 1496; and in September 1520, succeeded his father, Selim I. (q. v.), who had carefully initiated him into the secrets of Ottoman policy. At the commencement of his reign, he restored a large amount of unjustly confiscated property, and removed from office all who were unfit for the proper discharge of their duties. After having suppressed the revolt of the governor of Syria, he exterminated the Egyptian Mamelukes, and concluded a treaty with Persia. The foolish insolence of the Hungarian court next drew him thither with a powerful army, and Belgrade, the key of that country, was captured (1521). He next drove the Knights of St John from Rhodes (1522); and for three years following, devoted himself to improvements in the administration; but his attempts at military reform provoked a rebellion of the janizaries, which he saw no other means of quelling than by engaging them in a war with Hungary. He gained the signal victory of Mohacz (1526), and continuing his resistless course, took Buda and Pesth; but he was recalled by the news of a rebellion in the east, and retreated down the Danube to Constantinople, committing frightful ravages on the way. In 1529, he was summoned to Hungary in aid of his protégé, King John Zapolya, who was contesting the crown with Ferdinand, and accordingly invaded that country with a mighty army, capturing and destroying as he went, and laid siege to Vienna, but after various unsuccessful assaults, he was compelled to retreat. Two years afterwards (1531), he again appeared in Hungary; but his progress this time was checked by Charles V. in person, who had come with the imperial army of 250,000, in aid of his brother. In 1535, he concluded with Francis I. the famous treaty which opened the commerce of the Levant to the French flag alone. In 1540, the long and desultory contest between the Turks and Imperialists for Hungary was ended in favour of the former, who took

complete possession of the country. After this, the alliance between the French and Turks began to bear fruit; the combined fleets ravaged the Italian coasts, and pillaged Nice (1542); but peace was again restored with Germany in 1547. The Turks were now supreme in the Mediterranean; Gozzo and Tripoli fell into their hands, and the conquest of the Banat of Temeswar (1551) assured them a firm hold over Hungary. A second and third war with Persia, which was now in a state of semi-subjugation, the bloodthirsty ambition of his favourite wife Roxolana, who succeeded in persuading him to put to death the children of his other wives, a brilliant naval victory (1561) over the Knights of Malta and their allies the Spaniards, an unsuccessful blockade of Valetta in Malta (1565), and a fresh expedition to Hungary (1566), were the chief events of the remainder of his reign. During this last expedition, while besieging the little town of Szigeth or Szegedin, which resisted all his attacks, he died on the 5th September 1566. S. was no less a politician than a general; he was gifted with uncommon energy, kept his word inviolate, and if his successes were tarnished too frequently with deeds of cruelty, on the other hand, the enormous power at his disposal was infallible security for order and justice among all classes of his subjects. He was a lover of mathematics, and had a particular predilection for history. His financial administration was very successful, and he avoided carefully the two rocks upon which both before and since his time the prosperity of the Ottoman treasury has been wrecked—lavish personal expenditure, and negligence in scrutinising the public accounts.

SOMA ('the moon-plant,' or *Asclepias acida*) is, in the Vedic hymns, the god who represents this plant, and one of the most popular deities of the Vedic religion. The reason for this popularity must be sought for in the important part which the juice of the Soma-plant played in the great Vedic sacrifices, and probably also in its alcoholic and invigorating properties, which the sacrificer experienced when he drunk of it in the exercise of his functions. These properties are constantly described or alluded to in the hymns addressed to Soma. Thus, in some hymns, S. is said to exhilarate Varun'a, Mitra, Indra, and the other gods who partake of its juice; and in another, the worshippers exclaim: 'We have drunk the Soma; we have become immortal; we have entered into light; we have known the gods. What can an enemy now do to us, or what can the malice of any mortal effect?' In other passages, the juice of the Soma is said to be a draught of immortality, medicine for the sick, and a remedy for blindness and lameness. Thus S. became endowed with supernatural qualities and divine attributes, and gradually was exalted as one of the most powerful deities. He is the friend, helper, and soul of Indra; he is the slayer of the cloud-demon Vr'itra, the destroyer of foes, the dispeller of darkness, the creator of the sun, the upholder of the sky, and the sustainer of the earth, the king of gods and men; he is thousand-eyed, the most heroic of heroes; he is wise, strong, energetic, &c. See the interesting article on S. by John Muir, in his 'Contributions to a Knowledge of the Vedic Theogony and Mythology,' in the *Journal of the Royal Asiatic Society*, new series, vol. i. pp. 135, ff. In the classical period of Hinduism, S. ceases to be worshipped in the character which he has at the Vedic period; he then becomes the god of the moon. This transition from Soma, the plant and its juice, to Soma, the moon, which is perceptible even as early as in the S'atapatha Brâhmana of the White Yajurveda (see VEDA), is apparently due to the belief, that *Amr'ita*, the beverage of immortality, was guarded by the moon, and to the circumstance that, in the Vedic hymns, S. is frequently called or described as *Amr'ita*. The myths connected with Soma, the moon, are wholly different from those relating to the Vedic Soma. As moon, S. was born from the eyes of Atri, a son of Brahman, the first god of the Trimûrti (q. v.); and became installed by Brahman as the sovereign of plants, Brâhman'as, and planets. But after he had acquired extensive dominion, he became arrogant and licentious, and carried off Târâ (lit., a star), the wife of Vr'ihaspati, the preceptor of the gods. Vr'ihaspati seeking to recover his bride, and some of the gods siding with him, and others with S., a war broke out, which ended in Târâ's being restored to her husband. The result, however, of her stay with S. was the birth of a son named Budha, who became the ancestor of a celebrated dynasty of kings—from its origin, called the lunar dynasty. For kings of the solar dynasty, see SURYA.

SOMA'LI LAND, an extensive maritime country in the east of Africa, is triangular in shape, and is bounded on the N. by the Gulf of Aden, on the S.-E. by the Indian Ocean, and on the S.-W. by the Jub River. From the middle course of the Jub to Cape Guardafui, which forms the apex of the triangle, the distance is nearly 900 miles. The area of the country is estimated at 330,000 sq. m.; but as great part of its interior still remains unexplored, the number of its inhabitants has not been ascertained. The land is elevated and mountainous in the north, and slopes in terraces towards the south. The Jub, which forms the south-west boundary, is a large fertilising stream, drawing its waters from the mountains of Southern Abyssinia, and flowing south-east between the territories of the Gallas on the west, and those of the Somali on the east, to its mouth on the northern frontier of Zanzibar. The Webbe Shebéli, or Haines River, flowing south-east, and the Nogal, flowing east-south-east, are the other chief rivers. The country between the Jub and the Haines is well cultivated, and produces abundance of grain. Between the Haines and Nogal, the country is a flat grassy country, considered by the pastoral Somali a famous cattle district.

The present Somali race were originally Arabs, who landed on the African shore south of the Gulf of Aden early in the 15th century. Driving back the earlier inhabitants of the country, who were Christians, the Moslem made themselves masters of the country. The inhabitants are extremely violent and quarrelsome in their disposition, are notorious for cheating and lying, and for the most part pursue a wandering, pastoral life. The chief trading-place is Berbera, on the north coast; and the products of the country are sheep, cows, ghee, grass-made mats, ostrich-feathers, and hides. These are exchanged at the ports for cloth, dates, rice, beads, and iron.—*What led to the Discovery of the Nile*, by Captain Speke (Blackwood and Sons, Edinburgh, 1864).

SOMERSET HERALD. See HERALD.

SOMERSET HOUSE, in the Strand, London, stands on the site of a palace built by the Protector Somerset about 1549, which fell to the crown on Somerset's execution, and was at different times inhabited by Queen Elizabeth, Anne of Denmark, and Catharine, queen of Charles II. The original Somerset House was pulled down and rebuilt in 1776, after designs by Sir William Chambers, in the Palladian style, for public offices, apartments being given in it by the crown to the Royal Academy of Arts and the Royal Society. Various offices

connected with the navy and other public departments were removed there in 1788; and in 1813 the east wing was completed to form King's College. Among the government offices now in Somerset House are included various departments of the Admiralty, the Audit Office, the Inland Revenue department, the Bank Returns Office, the General Registry Office of Births, Marriages, and Deaths, and others.

SOMERSETSHIRE, a maritime county in the south-west of England, is bounded on the N.-W. by the Bristol Channel, and on the S.-W. and S. by the counties of Devon and Dorset. Area, 1,047,220 acres. Pop. (1861) 444,873. The coast-line exhibits low cliffs and marshy hollows alternately; and its chief indentation is Bridgewater Bay. The only important harbours are at the mouths of the Avon and Parret, which are the two principal rivers, and which, like the most of the other streams, flow through the county in a north-west direction. The most prominent features of the surface of S. are the Mendip Hills (q. v.) toward the north, and the Quantock Hills toward the west, extending from Taunton north-west to the sea, and rising in their highest point, called Will's Neck, 1270 feet above sea-level. Fens and marshes, called 'levels' on the shore of the Channel, are very numerous. Their appearance is monotonous and dreary, but they are fertile and exceedingly valuable as pasture-land. The wheat and barley grown around Bridgewater are famous; but in general, agriculture is in a backward state. The principal products are Cheddar and other cheeses and cider. The minerals are iron, lead, and zinc, and coal and building-stone. The county contains Bath, Wells, and a part of Bristol; Bridgewater, Taunton, Frome, Glastonbury, &c. It returns four members to the House of Commons.

SOMERVILLE, Mrs Mary, a lady distinguished by her extensive acquaintance with the physical sciences, was born in Scotland about the year 1780. Her father, Sir William George Fairfax, was a naval officer of considerable reputation, who commanded the *Venerable*, Admiral Duncan's own ship, in the action of Camperdown, and who was afterwards knighted, and advanced to the rank of Vice-admiral of the Red. Mary, his daughter, is said to have been educated at a school in Musselburgh, near Edinburgh. In 1804, she married Samuel Greig, captain and commissioner in the Russian navy, who, being fond of mathematical and astronomical studies, instructed his wife in those pursuits by which she has since become famous. In 1806, Captain Greig died; and in 1812, his widow married Dr William Somerville, of Edinburgh, who subsequently attained the rank of Inspector of the Army Medical Board, and Physician to the Royal Hospital, Chelsea. Mrs S. first became known to the scientific world by some experiments on the magnetic influence of the violet rays of the solar spectrum. Her scientific attainments soon procured for her the acquaintance of Lord Brougham, at whose suggestion she undertook to produce for the Library of Useful Knowledge a summary of the *Mécanique Céleste* of La Place. The work, however, exceeded its dimensions as first contemplated, and was published in an independent form in 1831, with a dedication to Lord Brougham. This work at once achieved for its authoress a high place among the cultivators of physical science. It was followed in 1834 by her treatise *On the Connection of the Physical Sciences*, dedicated to the Queen, and of which a highly flattering notice appeared in the *Quarterly Review* of the time, comparing its authoress to Hypatia and Madame Agnesi. This work has since passed through nine editions in English, and was translated into Italian and published at Florence in 1861. Mrs S.'s next work was her treatise on *Physical Geography*, in two vols. 12mo, published in 1848, and dedicated to Sir John Herschel. Five editions have been issued in English, and two in Italian. In 1869, appeared her work on *Molecular and Microscopic Science*, 2 vols. In 1860, Dr Somerville died, at the advanced age of 91, at Florence, where Mrs S. still continues to reside, in the enjoyment of excellent health and all her faculties, notwithstanding her advanced age.

SO'MMA, a town of Southern Italy, at the northern base of Mount Vesuvius, 9 miles east of Naples. Pop. 4268.

SOMMARI'VA DEL BOSCO, a city of Northern Italy, province of Cuneo. Pop. 4474.

SOMME (anc. *Samara*), a river of Northern France, rises near Font-Somme, in the dep. of Aisne, and falls into the English Channel midway between Boulogne and Dieppe. Its entire length is about 120 miles, of which one-half is navigable. Its chief tributaries are the Avre and the Luce, and the most notable places past which it flows are St Quentin, Ham (where Louis-Napoleon was confined), Peronne, Amiens, and Abbeville. By means of the canal of St Quentin, it is connected with the Seine and the Scheldt, and by the Crozat Canal with the Oise.

SOMME, a maritime dep. in the north of France, south of Pas-de-Calais, and north-east of Seine-Inférieure. It is formed out of part of Picardy and Artois, has an area of 2377 sq. m., and a pop. (1867) of 572,646. S. is for the most part quite level, and in some parts marshy; sandy towards the coast, but on the eastern frontier broken by spurs of the Ardennes. It is well watered, but the only river of consequence is the Somme. The dep. produces abundance of corn and garden-fruits; also beet-root, oil-yielding plants, and splendid carrots. The rearing of cattle is carried on to a great extent. The chief manufactures are velvets, woollens, cottons, linens, silk, leather, and tapestries, besides beer and cider.

SOMNAMBULISM (Lat. sleep-walking). Walking in sleep is the most palpable, but not the most marvellous characteristic of this condition. The person affected walks, rides, climbs, with the eyes shut or insensible; his movements are precise, cautious, leading him into positions of difficulty and peril, which, if perfectly alive to their real nature, or if acting under the influence of ordinary motives, he would avoid; and yet there appears to be a partial consciousness of surrounding objects, and an adaptation to circumstances. Individuals have, while in this state, performed long journeys on foot or horseback, paying tolls, avoiding obstacles; they have successfully descended into coal-mines; they have ascended in safety to the roofs of houses, have climbed rocky cliffs, and successfully robbed eagles' nests, during the night; millers, saddlers, grooms, sempstresses, have all performed their customary work with perfect exactitude, but without any recollection of their exertions or industry. Notwithstanding the accuracy with which many acts are performed, that particular senses may be dormant is proved by insensibility to loud noises, and by a cook eating cabbage which had been substituted for a salad which he had carefully and artistically prepared. The senses, in relation to the idea or train of ideas present to the mind, appear to be awake, and preternaturally acute. This fact has suggested the hypothesis, that certain faculties are wakeful, open to impressions, and actuated by volition; while others, and the mind in general, are plunged

in profound sleep and unconsciousness. This may be true, and is in harmony with the opinion, that the phenomena are an acted dream or delusion, and that what is seen, heard, or done, is the mere embodiment or repetition of former impressions or impulses, at the time before the mind. This may be illustrated by the case of the student narrated by the Archbishop of Bordeaux, who composed a sermon and wrote out music while asleep; read them over, made corrections, scratched out lines, substituted others, put in its place a word that had been omitted, and continued to do all this, although a sheet of pasteboard was interposed between the writing and his face; shewing that he was copying mental images, and not with the eye.

Somnambulism occurs in the sensitive and excitable, often in conjunction with other nervous affections, and is hereditary; so that it may be regarded as on, if not within, the boundary of disease.—Herbert Mayo, M.D., *On the Truths contained in Popular Superstitions;* Macnish, *Philosophy of Sleep;* Binns on *Sleep.*

SOMNAU'TH, or SOMNATH-PUTTEN, a town of Guzerat, in Hindustan, is situated on the south-west coast of the peninsula of Kattywar (q. v.), about 33 miles from its southern extremity, and has at present a pop. of 5000, most of whom are Mohammedans. The town is fortified by a strong stone wall 9 feet thick, strengthened by 38 towers; it contains many mosques, and the ruins of the celebrated Hindu temple of the idol Somnauth. The ruins of the temple are in a state of fair preservation, and give the idea of its having been a gloomy, massive temple in the form of an oblong hall 96 feet by 68 feet, crowned by a magnificent dome, and covered on the inside and outside with elaborate sculpture and carving illustrative of mythological subjects. The splendour of this temple has doubtless been much exaggerated by various travellers; but a thousand years ago it was so famous as a place of pilgrimage for pious Hindus, as well as for its immense wealth—the accumulations of centuries of presents—that it attracted the zealous idol-destroyer, Mahmud of Ghizni, after he had accomplished his self-imposed mission of conquest, spoliation, and conversion in the rest of Northern India. In 1024, he appeared before S., drove its defenders—who at first had been buoyed up with sanguine hopes that their favourite god had drawn the Mohammedans hither that he might blast them with his wrath—to take refuge in the temple, where they defended themselves with such valour, that Mahmud's army was forced to retreat; but the subsequent rout of two Hindu armies which had advanced to the aid of the sacred city, so dispirited the defenders, that S. was immediately surrendered, the idol destroyed, and the enormous wealth of the temple, consisting chiefly of precious jewels, carried off, along with the gates of the temple. These gates, which are said to have been made of sandal-wood, were brought back from the entrance to Mahmud's tomb in Afghanistan by the British in 1842, and their recovery announced in a magnificent proclamation, which called upon the chiefs of Sirhind, Rajputana, Malwa, Guzerat, to transmit them 'with all honour' to the place whence, eight centuries ago, they had been violently removed. They were, however, never restored to S., as the home authorities disapproved of the tenor of the proclamation, fearing that it might stimulate religious animosity between the two great religious bodies of Hindustan. There was also reasonable ground of doubt as to whether the gates were really the original gates of S., and even whether (since the *Ferishta* does not mention the circumstance) Mahmud had taken away any gates. The repute of S. as a place of religious pilgrimage, and its wealth, revived some time after its spoliation by Sultan Mahmud, to such an extent as frequently to attract the various Mohammedan robber-princes of Western India; and it is still at the present day a chief resort of pious Hindus from all quarters, who pay a small tribute to the Guicowar for liberty to perform their devotions at this favourite shrine.—See Price's *Mohammedan History*, vol. ii.; Dow's translation of the *Ferishta;* Mirkhond's *Rauzat-al-safa*, and Sir John Malcolm's *History of Persia*, vol. i.

SONA'TA, a musical composition for a solo instrument, sometimes accompanied by one or two other instruments, consisting of three, four, or even more movements; these movements usually consist of a subject or subjects, given out first in the key of the dominant, and after certain episodes, in which these themes are presented in a great variety of aspect, they are repeated in the key of the tonic. This form is in general most closely adhered to in the first movement of a sonata, and exhibits great room for a display of the inventiveness and musical resources of the composer. The second movement is generally slower and shorter than the rest, and often in the form of a theme with variations. The most important compositions of this kind are for the pianoforte, many of which have been written by Haydn, Mozart, Beethoven, Clementi, Dussek, and other masters.—A short sonata with two, or at most three movements, less elaborately worked, is called a *Sonatina.*

SO'NCHUS. See Sow Thistle.

SO'NDERSHAUSEN, the chief town of the principality of Schwarzburg-Sondershausen, pleasantly situated on the Wipper, 36 miles north-west of Weimar. Pop. 5000.

SONG, a short poem adapted to a vocal melody. The word is generally applied to the poetical and musical composition in union, but sometimes to one or other separately. The poem generally turns on some single thought or feeling, and is divided into portions of returning measure. The term song, properly implying an air of a simple kind, is often, though not very correctly, applied to the elaborate *aria* of the opera, or the solemn air of the oratorio. A song generally implies an air for a single voice—airs for more than one voice being, however, sometimes called part-songs. England produced in the course of last century a large number of beautiful songs. Of the numerous songs which are continually appearing in this country at the present day, extremely few have musically much merit, and in a large proportion of cases the words are of a silly and insipid description. Germany has of late produced a larger proportion of beautiful songs than any other country. Among songs, not the least interesting are the national and popular airs of different countries, generally of uncertain date, and almost always possessed of much character.

SONG OF BIRDS. All birds have some voice or cry which they utter, and most of them various notes appropriate to various occasions. The power of producing clear and sweet musical notes is chiefly found in certain families of the order *Insessores;* some of which, as the lark, pour forth their song in the air; but the greater number, like the thrush and nightingale, sit whilst they sing. The compass and variety of notes, the power of trilling and shaking, the loudness, clearness, and sweetness of the song, differ very much in different species, each of which may be as perfectly recognised by its song as by its form or plumage. There are also, as is well known, great differences among individuals of the same species, and Mr Jesse asserts his confidence that

there are notable differences between the song of the birds of the same species generally in one district and in another, just as there are provincial dialects and modes of pronunciation in human speech. 'The song, for example, of a thrush near London, or in any of the home counties, has little resemblance, except in specific character, to that of the same bird in Devonshire or near Exeter. The same notes, I suppose, will all of them be detected, but they are arranged for the most part into a different tune, and are not sung in the same way. They are given with different values, and the singing is pitched in a different key. One great distinction between the two cases is the number of guttural notes of which the song of a Devonshire thrush is often made up, but which near London are heard only at the end of a bar, or even much less frequently; while those chief notes, which mainly constitute the song of the other bird, and make it so impressive, are rarely pronounced by the Devonshire thrush.'—*Scenes and Occupations of Country Life*, p. 112.

The singing of birds is chiefly connected with the love-season; although some birds sing at other seasons also, during fine weather, and when food is abundant, as if merely to utter their happiness, and by uttering, to increase it. It is during the pairing-time that they are most vocal; the singing of many is continued with frequency also during the period of incubation, but with some change of character. It is the male alone that sings. Female birds have voice also, but do not possess the power of warbling like their mates. There are generally considerable anatomical differences in the larynx of the two sexes.

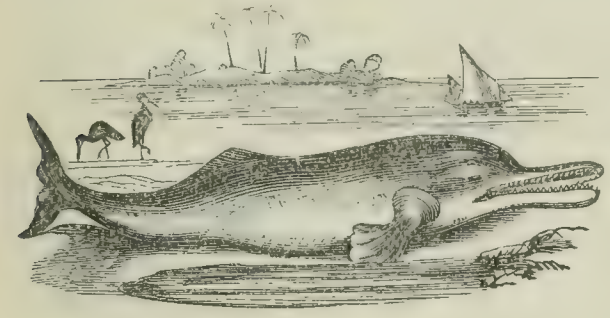
There can be no doubt that the singing of the male bird is intended to attract and please the female, and that he delights in this display of his own powers. In this respect, there is no difference between the birds of most melodious song and those of harsh discordant voice. The crowing of the cock and the gobbling of the turkey have the same purpose as the song of the nightingale. In them may be also seen an emulation which is ready further to display itself in combats, and probably these take place among the males of all birds. But questions of rivalry seem in part to be decided amongst some of the songsters of the groves by mere musical displays. Caged birds evidently often sing from emulation. Remarkable proofs of the extent to which this feeling prevails with regard to the musical powers, are afforded by well-authenticated anecdotes.

The imitative powers so remarkably possessed by the mocking-bird and a few other species, are to some extent possessed by many birds.

SONGHAY, a former kingdom of Africa, extended both on the east and west banks of the river Niger to the south of the angle which that river makes at Burrum, in lat. 17° 30′ N. The reigning king, said to have been the fifteenth of his dynasty, embraced Islam in the beginning of the 11th century. In 1468—1469, the ruler of S. marched upon Timbuktu, conquered the town and surrounding state, and added them to his own kingdom. Under Háj Mohammed A'skia, who came into power at the end of the 15th c., and who was perhaps the greatest sovereign that ever ruled over Negroland, the S. empire extended from Hausa almost to the shores of the Atlantic, and from lat. 12° N. to the confines of Morocco. After many years of revolution and civil war, this great empire became a province of Morocco in 1607.

SO'NNET, a short poetical piece, generally lyrical in its nature, and dealing with *one* idea of a grave nature, presented under various aspects. It is restricted in length to fourteen lines; the arrangement of the rhimes is peculiar and intricate, and will be best understood by an example—Wordsworth's Sonnet on the Sonnet—

> Nuns fret not at their convent's narrow room;
> And hermits are contented with their cells;
> And students with their pensive citadels:
> Maids at the wheel, the weaver at his loom,
> Sit blithe and happy; bees that soar for bloom,
> High as the highest peak of Furness Fells,
> Will murmur by the hour in foxglove bells.
> In truth, the prison, unto which we doom
> Ourselves, no prison is: and hence to me,
> In sundry moods, 'twas pastime to be bound
> Within the Sonnet's scanty plot of ground:
> Pleased if some souls (for such there needs must be)
> Who have felt the weight of too much liberty,
> Should find short solace there, as I have found.



SON OF GOD. Considered from the side of dogmatic theology, the phrase Son of God denotes the Second Person of the Trinity (q. v.), and is conceived to have been applied to him on account of that subordination to the Father, to which from all eternity he voluntarily submitted, and which, it is thought, peculiarly fitted him for accomplishing the work of redemption. If we examine the use of the name in the Scriptures, it appears to have been both applied by Jesus to himself, and given to him by his disciples, to express a singular and mysterious relationship in which he stood to God. The phrase was one not altogether unknown to the Jews. The plural, 'sons of God,' occurs several times in the Old Testament (Gen. vi. 2, 4; Job i. 6, ii. 1; Psalm lxxxii. 6, &c.); but in all these cases it is applied (tropically) to angels or persons possessing some exalted dignity; and the children of Israel, in their collective capacity as the favoured nation, are twice called by God his 'son' (Ex. iv. 22, 23; Hosea xi. 1). The use made in the New Testament of the famous passage of the 2d Psalm ('Thou art my Son; this day have I begotten thee') is thought to constitute conclusive evidence that the spiritually-minded among the ancient people recognised a 'Son of God.' The only direct and literal occurrence of the phrase 'Son of God' is found in the Book of Daniel (iii. 25, 'The form of the fourth is like the *Son of God*'), and this singular circumstance has suggested the idea, that the Hebrew conception of a Messiah or anointed deliverer was first connected and combined with the still grander conception of a divine nature under Assyrian or Persico-Assyrian influences. If, it is argued, the Hebrews generally, or even their spiritual leaders, had believed the Messiah to be the 'Son of God' in any other sense than that he was prophetically filled with the Spirit of God, both the idea and the phrase would have played a far more prominent part than they do in the religion and literature of the nation. Nor does it appear that the idea of a 'Son of God' (in the literal sense) ever rooted itself in the Hebrew mind, which, from its sublime conviction of the unity of God, seems to have always regarded this approach to dualism in the Godhead with peculiar aversion. Hence, we find that the assumption of the title by Jesus provoked the bitterest opposition on the part of the great majority of his countrymen. They did not hate him because he claimed to be the 'Messiah,' the 'Christ;' on the contrary, they were prepared to accept as such any teacher whose words or works seemed to justify his pretensions to the dignity; but when Jesus claimed to be the 'Son of God,' equal and one with the Father, they sought to stone him. It was, in fact, this assertion of his divinity that cost Jesus his life.

SONO'RA, a frontier state in the north-west of Mexico, bounded on the N. by the United States' territory of Arizona, and on the W. by Lower California and the Gulf of California. Area, 131,117 sq. m.; pop. (in 1869) 147,133. Several fine bays indent the coast; lagoons occur near the shore; and in the western part of the state, there are several lakes. The great system of the Andes skirts the eastern frontier, and throws off branches which occupy much of the surface of the state. In the west, the surface is mostly flat, with a fertile soil, and a warm but variable climate. The chief rivers are the Rio Colorado, Ignacio, Yaqui, and Mayo. Two abundant crops are gathered every year from the same land; and the principal crops are wheat, maize, peas, and beans; though tobacco, sugar-cane, and cotton are also grown. But the wealth of the state is not in its agricultural capabilities, but in its mineral treasures, which are considered inexhaustible. 'Hardly a village or grazing estate,' writes a recent traveller, 'but can shew some vein of gold, silver, lead, or copper;' and he thinks that in all probability 'not a fourth of its existing metallic wealth is known, while not a moiety of that has been or is being developed.' The inhabitants of S. are for the most part degraded, indolent, and uneducated, and among them mining enterprise has now reached its lowest ebb.—See *Arizona and Sonora*, by Sylvester Mowry (Lond. 1864).

SONSONA'TÉ, a town of Central America, in San Salvador, and 40 miles west-north-west of the city of that name. Pop. about 10,000 inhabitants.

SOOLOO' ISLANDS. See SULU ISLANDS.

SOO'SOO (*Platanista Gangeticus* or *Soosoo Gangeticus*), a cetacean of the Dolphin family, inhabiting the Ganges, and most abundant in the sluggish waters of its delta, but found also as far up the river as it is navigable. It is supposed to be the

Soosoo (*Platanista Gangeticus*).

Platanista of Pliny. It is the only known existing species of its genus, and is interesting as a fresh-water cetacean. It attains the length of about 12 feet, and is not unlike the dolphins in its general form. The habits of the S. are sluggish, except that in pursuit of prey it moves with great energy and rapidity. The flesh resembles lean beef, but is never eaten by the Hindus, who, however, set a great value on the fat, which lies between the skin and the flesh, as an external medicinal application. There are several fossil species of this genus.

SOOT is that portion of fuel which escapes combustion, and which is mechanically carried up by the current of hot air, either to be deposited on the sides of the chimney, or to be discharged into the atmosphere. The soot of coal and that of wood in all probability differ materially, the former containing more carbonaceous matter and more ammoniacal salts than the latter. Braconnet published an elaborate analysis of the soot of wood; but good recent analyses of both kinds of soot are still required. Both kinds are used as manure; and wood-soot, under the title *Fuligo Ligni*, was formerly contained in the British Pharmacopœias. According to Neligan, it has been found most efficacious in the latter stages of hooping-cough in children, and in some forms of hysteria; and he gives directions for the preparation of a Decoction, an Extract, a Spirit, and a Tincture. See Neligan's *Medicines*, &c. (6th ed., p. 53). Contact with soot often gives rise to a peculiar form of cancer, which is consequently known as *Chimney-Sweepers' Cancer*.

SOPHI'A, a town of Bulgaria, 170 miles north-west of Adrianople, in a beautiful plain on the river Isker. Besides about 30 mosques, it contains several Christian churches, is the see of a Greek and a Roman Catholic archbishop, and carries on manufactures of cloth, leather, silk goods, and tobacco. Its hot springs and baths are highly esteemed. Pop. 24,000. S. occupies the site of the ancient Sardica.

SOPHIA, ST., CHURCH AND MOSQUE OF, a celebrated structure at Constantinople, long an object of great interest to all visitors of that city. It was originally built by the Emperor Constantine in 325—326, on occasion of the translation of the seat of empire to Byzantium; and is so called as being dedicated, not, as commonly supposed, to a saint of that name, but to the *Hagia Sophia* (Holy Wisdom), that is, to the Eternal Wisdom of God or the Logos, the Second Person of the Trinity. The building of Constantine was subsequently rebuilt and enlarged by his son Constantius; and this second church of Constantius having been destroyed in 404, was rebuilt by Theodosius the Younger in 415; and it lasted unaltered till the celebrated Nika Sedition, or Battle of the Factions of the Circus, under Justinian, in 532, in which it was totally destroyed. The present building is substantially that which was erected by Justinian in expiation of this sacrilege. It occupied less than seven years in its erection, and the history of the work and of the details of its material and construction are full of marvels. Ten thousand workmen are said to have been employed upon it. The materials were supplied from every part of the empire, and comprised remains of almost every celebrated temple of the ancient paganism. The sedilia of the priests and those of the patriarch were of silver gilt. The dome of the tabernacle was of pure gold, and was surmounted by a gold cross weighing 75 lbs., and encrusted with precious stones. All the sacred vessels and other apparatus were of gold. The altar-cloths were embroidered with gold and pearls; and the altar itself was composed of a mass of molten gold, into which were thrown pearls, sapphires, diamonds, onyxes, and every other object which could raise its costliness to the highest imaginable degree. The total cost of the structure is stated by the ancient authorities at 320,000 *pounds*. Some regard this as pounds-weight of silver, others as of gold. One of the latest writers on the subject, Mr Neale (*Eastern Church*, vol. i. p. 237), adopts the latter estimate, and thus computes the cost at the enormous sum of £13,000,000!

The building may be described as a square of 241 feet, forming interiorly a Greek cross, and surrounded in the interior by a woman's choir or gallery, supported by magnificent pillars, for the most part borrowed from ancient buildings. In the centre rises a dome, which is supported by two great semi-domes, which in their turn rest upon smaller semi-domes, the whole presenting a series of unexampled beauty. The height of the dome is 175 feet. The building is approached by a double

porch, which is about 100 feet in depth. The whole of the interior was richly decorated with sculptured marble and mosaics. Even in the reign of Justinian, a further reconstruction of the building became necessary, the dome having fallen in, on an earthquake; but this may be said to have been the last important change in the structure within the Christian period of Constantinople.

On the occupation of that city by the Turks in 1453, St S was appropriated as a mosque. All its purely Christian fittings and internal structures were swept away. The Christian emblems were either mutilated or covered up from view by a coating of plaster. The latter course was adopted throughout the building in the case of mosaic pictures containing representations of the human figure, which the Koran proscribes as unlawful, and thus the original mosaics of the Justinian era have in great part escaped destruction. Some years since, the late sultan, Abdul Medjid, having ordered a complete restoration of the building, these mosaics were accidentally brought to light, and, with the consent of the sultan, artists were sent out from Berlin, who, with the assistance of the architect employed by the Turkish government, made accurate copies of all these interesting relics of antiquity, which have been published at the expense of the Prussian government by M. Salzenberg, the artist thus employed by the king. The interior of the building at present is very judiciously restored for Mohammedan worship, the Christian decorations being again carefully covered up, coated with plaster in imitation of mosaic-work. Like all mosques, St S. is closed against Christian visitors except upon special firman, which, however, is easily obtained, and the privilege may be had at small expense by the traveller through the interposition of the masters of the principal hotels.—See Von Hammer's *Constantinopolis und der Bosporos* (2 vols. 8vo, Pesth, 1822); Salzenberg's *Alt-christliche Baudenkmale Konstantinopels* (Berlin, 1854); Haghes, *Aya Sofia Constantinople* (London, 1854); also *Edinb. Review*, April 1865, p. 456, and foll.

SO'PHISTS. The Sophists were the leading public teachers in ancient Greece during the 5th and 4th centuries B.C., and their character has been a subject of much dispute. Most of the historians of philosophy—influenced seemingly by the lampoons of Aristophanes, the comic poet, and by the disparaging remarks of Socrates, Plato, and Aristotle, who stood in a quite different position from the teachers by profession—represent the Sophists as 'ostentatious impostors, flattering and duping the rich youth for their own personal gain, undermining the morality of Athens, public and private, and encouraging their pupils to unscrupulous ambition and cupidity.' Mr Grote, in his *History of Greece*, chap. lxvii., has combated these positions, and given a much more favourable view of the Sophists.

A Sophist, in the original sense of the word (derived from *sophos*, wise or learned), was a wise man, a clever man, one who stood prominently before the public for intellect or talent. Solon and Pythagoras are called Sophists; the name was applied even to great poets. Socrates was repeatedly so designated; Plato is alluded to by the same title. By the general public, any man of intellectual eminence would be spoken of as a Sophist. With the feeling of admiration towards the intellectual class, there was mixed up a certain invidious sentiment, from whatever cause arising; and the name Sophist being often used to express the dislike as well as the admiration, came ultimately to have a predominating bad sense. Still, the general public, in the use of the word, comprehended Socrates, Plato, and Aristotle, and their philosophical disciples and followers, equally with the professional teachers.

The great intellectual start made in Greece during the 5th c. B.C., led to an advanced standard of general instruction. There had been an established popular education long before—including music, reading, and recitation—but now there were found among the public teachers men of the highest accomplishments that the age could furnish, who taught whatever was known of astronomy, geography, and physics, as well as the newly started controversial discussions in ethics and in metaphysics. These men shared with the other intellectual celebrities the title of Sophist. But there was one circumstance in their case that greatly deepened the invidious sentiment—they taught for pay. This brought them under the odium of two classes: in the first place, the poor, who could not afford the fees, felt themselves in a new position of inequality with the rich; secondly, the philosophers, properly so called, who had not yet begun to receive money from their disciples, held in contempt those that did. Both Socrates and Plato had a vehement repugnance to the idea of a money-bargain between master and pupil; in their eyes, the relationship was one of pure attachment and devotion; and they considered that all the invidious part of the designation Sophist, and more, was richly deserved by the teachers for hire; and as these public teachers, by the nature of their vocation, would probably be often shallow and superficial, as compared with the great philosophers, we can understand the full definition of Sophist by Aristotle—'an impostrous pretender to knowledge, a man who employs what he knows to be fallacy, for the purpose of deceit and of getting money.' With all the great authority of Aristotle, this charge applied indiscriminately to the body of men employed in training youth for active life, will not bear investigation. Enough is known of the lives, characters, and doctrines of the class to refute the accusation. The Sophists were a profession growing out of the circumstances, and supplying a want, of the age. The most valuable ideas and habits of any accomplished Athenian were due to his education under some teacher of the class Rhetor or Sophist. So far from the age of the Sophists being an age of corrupted public morality, Mr Grote contends that it was the reverse. He adduces a multitude of historical facts to prove that the morality of the Athenian public was greatly improved at the end of the 5th c. B.C., as compared with the beginning of that century.

SO'PHOCLÉS, the great master of Greek tragedy, was born at Colonus, a village about a mile from Athens. The date of his birth is not exactly known, but is fixed at 495 B.C. Sophillus, his father, a man of good birth and fortune, bestowed much care on his son's education; insomuch that, aided by his highly prepossessing appearance, S. was selected for his skill in poetry and music to lead with dance and the lyre, after the victory of Salamis, the chorus of youths in a triumphal pæan composed by himself. In his 28th year, he is said to have *exhibited* his first play; and three years before, in a contest with rival scenic writers, one of whom was Æschylus, he gained the first prize, by the decision of the judges Cimon and his colleagues. He had, by Nicostrata, two sons, and one by Theoris, a Sicyonian woman. Iophon, one of his two sons by Nicostrata, summoned him in his old age before the Phratores, on the charge of incapacity to manage his private affairs, but he refuted the charge by reciting to the court a beautiful chorus from his *Œdipus in Colonus*. He died at the age of 90, full of years and honours. His private character

was easy and contented, but not, as has been hastily assumed, profligate. His turn of mind was devout, as is evident throughout his plays; and he evinced no taste for political or active life, although he is said to have accepted command in the Samian war. He was a prolific author. He was the reputed composer of as many as 130 plays, of which, however, 17 have been deemed spurious. He gained, according to his biographer, the first tragic prize 20 times, bearing the palm on several occasions from Æschylus and Euripides, not to mention less well-known competitors. He wrote also pæans, elegies, and epigrams, of which we have but few remains. He lived on terms of intimacy not only with his great rivals, but with Aristophanes and Herodotus. We have no knowledge of the order in which his plays, that have survived, were written. The most plausible arrangement is perhaps that of Müller, who graduates them as follows: *Antigone*, *Electra*, *Trachiniæ*, *Œdipus Rex*, *Ajax*, *Philoctetes*, *Œdipus Coloneus*. S. is justly accounted the most perfect of the Attic tragedians. In his hands, tragedy becomes the true and faithful reflex of human feelings, passions, impulses. His ideas are ethical, with a constant reference to a divine disposer of events. 'There has hardly,' says Müller, 'been any poet whose works can be compared with those of Sophocles for the universality and durability of their moral significance. Of all the poets of antiquity, he has penetrated most deeply into the human heart.' His versification is remarkable for its softness and fluency. The best editions are those of Wunder (Gotha and Erfurt, 1831—1846) and Schneidewin. The chief translations of S. into English are those of Potter (Lond. 1788), Dale (Lond. 1824), and recently (1865) of Plumptre. Besides these we may mention special translations by Professor D'Arcy Thompson of the *Ajax*, and by Dr Donaldson of the *Antigone*.

SOPRA'NO (Ital.), the highest species of female voice, whose range extends from  to  , or in some cases higher. The highest notes generally belong to the falsetto register. Sweetness and mellowness are the characteristic qualities of a soprano voice, which is for the most part less full than an alto, but lighter, fresher, and more expressive of joyful, lively, and highly impassioned feelings. Music for soprano voices is usually written in the treble clef, but sometimes in the soprano clef with C on the first line  . A voice sometimes distinguished as intermediate between alto and soprano, is the *Mezzo-soprano*, whose usual compass is from  to  .

SO'RA, a city of Southern Italy, in the province of Terra di Lavoro, with 8768 inhabitants. It stands in a fertile plain, watered on one side by the Liris or Garigliano, which is spanned by two bridges at the town. The population is industrious and wealthy. There are manufactories of woollen cloth and of paper. S. was originally a Volscian town, passed into the possession of the Samnites, and then into that of the Romans. Remains of the cyclopean walls of the ancient citadel are still visible.

SO'RAU, a town of Prussia, in the province of Brandenburg, 60 miles south-south-east of Frankfurt-on-the-Oder. It has important bleach-fields, print-works, and colour-works. Pop. 11,264. S. is one of the oldest towns in Prussia.

SORB. See SERVICE.

SORBONNE, a celebrated academic body at Paris, which dates from the middle of the 13th c., and which, down to the French Revolution, held a prominent place in every doctrinal, liturgical, or canonical controversy which arose in the church. It derives its name from its founder, Robert de Sorbon, a canon of Cambrai, born of a humble family, in the village of Sorbon, in the Ardennes, in 1201. Being recommended by his learning and virtues to Louis IX., he was selected by that king as his chaplain and confessor. At this time, the university of Paris was at the very height of its celebrity, and Robert de Sorbon conceived a project for rendering its advantages accessible to poor students, by opening an institution in which a society of secular priests, being provided with all the necessaries for their own maintenance, should devote themselves gratuitously to the teaching of theology. It was established with the full sanction and warm encouragement of King (afterwards St) Louis in 1252, originally for the reception of sixteen scholars, four respectively from the Gaulish, Norman, Picard, and English nations, to which the German was subsequently added. Robert was himself the first head; but it was not till after 18 years that he drew up the constitution of the association, which, it may be added, remained in force without any substantial alteration till the French Revolution. The institution was not confined to the poor scholars of the original establishment, but extended to the bachelors and doctors aggregated to the body of the Sorbonne. All these were of necessity graduates of the Faculty of Theology of the university of Paris, but they were only admitted to membership of the Sorbonne by the votes of that body, which formed one of the four constituent parts of the Theological Faculty, and after a public disputation, technically called the 'Sorbonica,' or 'Robertina,' in which the disputant was required to sustain, against all antagonists, from the hour of five in the morning to that of seven in the afternoon, theses or propositions selected from the whole range of theological science. The first recorded actor in this great theological tournament was a Franciscan friar named Mayron, a scholar of John Duns Scotus; but he was followed by a long roll of imitators, in which are found many of the greatest names in medieval and post-reformation history. These 'Sorbonne Acts' form in some respects one of the most characteristic chapters in medieval literary history, the succession of disputants and the variety of subjects being altogether extraordinary. The disputants in some cases exceeded sixty in number. The foundation of Robert de Sorbon was approved in 1268 by Clement IV.; but the name of Sorbonne does not appear to have been appropriated to it till some time in the course of the 14th century. Robert de Sorbon also established another college for the study of the Humanities and Philosophy, which was called the college of Calvi, or the Little Sorbonne, and seems to have been preparatory to the Sorbonne course of study. In the 15th c., the Sorbonne, as being in great measure identified with the Theological Faculty of the Paris University, holds an important place in the history of theological controversy, and in all the contests which followed the Reformation in France, it holds a foremost rank; there being few of the great names of the Gallican Church which are not included in its academic roll. Among the munificent works of the great Cardinal Richelieu, who was a pupil of the Sorbonne, was what may be described as a complete reconstruction of the

buildings. The new Sorbonne comprised, in addition to the public academical hall, lodgings for the 36 doctors, which were assigned to the doctors successively in the order of seniority. The head of the Sorbonne institute was called Provisor, and was elected by the members, together with the Archdeacon of Paris, the four Deans of Faculty, and some other dignitaries of the university. Besides the resident members of the Sorbonne, there were also external associates, called 'Socii Hospitalitatis,' who had no share in the deliberations of the body or the governmental acts of the institution. The Sorbonne continued in the enjoyment of its privileges and its revenues down to the Revolution, when it shared in the common ruin of all the ecclesiastical establishments of France. At the reorganisation of the university by Napoleon in 1808, the Sorbonne was re-established as the Theological Faculty of that body; but it failed to recover its old prestige even with the clerical body. One of the conditions of membership was an oath to maintain the celebrated four 'Gallican Propositions.' See GALLICAN CHURCH. This condition deterred many; and although it was revoked by the proposed concordat of 1817, yet, on the failure of this concordat, it still continued in force down to the revolution of 1830. In the more recent organisation of the university, the Sorbonne has no distinct or special character; but its halls still retain their ancient appellation.—See Wetser's *Kirchen-lexicon*, 'Sorbonne.'

SORE'CIDÆ, a family of Mammalia, of the order *Carnaria*, and section *Insectivora* of Cuvier. They are generally small animals, covered with soft hair; under which, on each flank, is a band of stiff closely-set bristles, and among them glands which exude a peculiar odorous fluid. The legs are short, and the feet are five-toed, and generally formed for burrowing. Some species are aquatic, and their feet webbed. The S. are all plantigrade. Most of them are nocturnal animals. They generally feed on insects and worms. A remarkable characteristic of the family is the elongated muzzle. They have long incisors, and their molar teeth are generally furnished with conical points. The tail is generally scaly. To this family belong Shrews, Shrew-mice, Musk Rats or Desmans, &c. They are found both in warm and cold climates. Those which inhabit cold climates generally pass the winter in a lethargic or dormant state.

SORESI'NA, a large mercantile town of Northern Italy, province of Cremona, with 6767 inhabitants. A great trade is carried on in a kind of condiment called *Mostarda*, which is prepared there, consisting of fruits, &c., preserved in vinegar and sugar, and also in a kind of liqueur called *Mistrà*, held in great repute in Italy as a carminative.

SO'RGHO GRASS AND SORGHUM. See DURRA.

SO'RIA. See NUMANTIA.

SOROCA'BA, a town of Brazil, in the province of São Paulo, stands on a river of the same name, 70 miles west of the city of São Paulo. Pop. 12,000.

SO'RREL (*Rumex*), a genus of plants of the natural order *Polygoneæ*, very closely allied to *Polygonum* (q. v.) and *Fagopyrum* (see BUCKWHEAT), but having the perianth divided into six segments, the three inner of which enlarge and cover the *achenium*. The genus is very naturally divided into two sections, the first of which is already noticed in the article DOCK. The name S. belongs only to the second, characterised by dicœcious flowers, and acidity of stems and leaves. COMMON S. (*R. acetosa*) is a perennial found in meadows and pastures throughout the whole of Europe, and is very plentiful in America. Its stem is from a foot to two feet high; its leaves arrow-shaped. It is an agreeable salad, and is used in soups and sauces, and as an addition to dishes of greens. It is therefore sometimes cultivated in gardens.—FRENCH S., or ROMAN S. (*R. scutatus*), a native of France and Italy, has broader and blunter leaves, and is more frequently cultivated than Common S., being considered of finer flavour.—SHEEP'S S. (*R. acetosella*) is a very similar plant, but of much smaller size, and its roots run very much under-ground, so that it is a very troublesome weed in gardens and fields of poor dry soil, in which it is very common in all parts of N. United States.—For WOOD S., see OXALIDEÆ.—For the RED S. of the West Indies, see HIBISCUS.

SORREL TREE (*Lyonia arborea*, formerly *Andromeda arborea*), a tree of the natural order *Ericeæ*, remarkable in that portion of the order to which it belongs for its magnitude, its near allies being generally small shrubs. It grows chiefly on the Alleghany Mountains, from Virginia to Georgia, and attains a height of 50 feet, with a trunk 12—15 inches in diameter. The wood is of little or no use. The leaves are acid, and are sometimes used for dyeing wool black.

SORRE'NTO (Lat. *Surrentum*, Gr. *Syrentum*), a maritime town in the south of Italy, province of Naples, is situated on the south-east side of the beautiful Bay of Naples, on the promontory which separates the latter from the Gulf of Salerno, about 7 miles south-west of Castellamare. Pop. 7180. It is an archiepiscopal see, and possesses a cathedral. The manufacture of silk is extensively carried on. There are still considerable remains of the walls which were erected in the middle ages, and on the landward side it is surrounded by a broad and deep ravine, the side towards the sea being protected by precipitous rocks. On the north-west of the town is a considerable plain or table-land, called *Piano di Sorrento*, about 1000 feet above the sea-level, surrounded and protected from the cold east winds by a range of hills; it is intersected by numerous gorges and ravines, studded with villas and farm-houses, and covered with orange groves and vineyards; all which combined render the vicinity of the city in a high degree picturesque. It is celebrated for the mildness, dryness, and general salubrity of its climate, on which account it has been much resorted to both in ancient and modern times by invalids and convalescents. Among the Romans, the wine of S. was held in high reputation; it had to be kept about 25 years before it arrived at maturity. Nothing certain is known of the origin of S., but it is believed to be very ancient, and many ruins are pointed out by the *ciceroni* as being remains of Roman temples, &c. Tasso was a native of Sorrento.

SO'RTES BI'BLICÆ, SORTES VIRGILIA'NÆ, &c.—Among the ancients, a favourite kind of divination was that known as *Stichomancy*, or divination by lines of poetry. The method pursued was to select a number of verses from a poet, mix them together in an urn, draw one out at random, and from its contents to infer good or evil. As Virgil was the most popular and admired of all the Latin poets, his writings, and especially the *Æneid*, became the favourite book for this purpose, and it was undoubtedly this practice that laid the basis of the great reputation as a magician Virgil enjoyed during the middle ages. The Sibylline oracles were also much used for the same purpose. The practice did not cease with the introduction of Christianity; but instead of Virgil, or, to speak more correctly, alongside of Virgil, the Bible was

employed to ascertain the future. In place, however, of throwing lines into a 'heathen' urn, it was customary to open the book, as it were, accidentally, or to stick a pin between the leaves at hazard, and then open the book—the passage first catching the eye being regarded as pregnant with prophecy as to your future welfare. Such lots drawn from Scripture were called, in the middle ages, *Sortes Biblicæ*, just as those drawn from Virgil were called *Sortes Virgilianæ*. The custom of using (or abusing) the Bible in this grossly superstitious way still lingers in England, Scotland, and other countries, but it is now more a frolic of children than aught else.

SO'RTIE, an outrush of a beleaguered garrison, equivalent to SALLY (see SALLY-PORT).

SORUS. See FERNS.

SOSTENU'TO (Ital.), a term used in musical notation, to indicate a sustained mode of execution, continuous in respect of tone.

SOTTEVILLE-LÈS-ROUEN, a small town of France, in the dep. of Seine-Inférieure, 4 miles south of Rouen by railway. Pop. (1862) 8182.

SOU, or SOL. See SOLIDUS.

SOUARI NUT. See CARYOCAR.

SOUDAN. See SUDAN.

SOUFFLÉ, a light and agreeable dish, consisting chiefly of the whites of eggs, to which other ingredients (chocolate, cheese, vanilla, orange-flower water, rose-water, various essences, &c.) are added, to give consistency, flavour, and variety. The materials have to be agitated with a whisk until the whole is in a creamy froth; which is then baked in a soufflé-pan, made of such a form as to fit into a dish or proper holder, that can be sent to table, and quickly handed round.

SOUKCHOU'M KALE', a seaport town of Asiatic Russia, in the government of Transcaucasia, on the east coast of the Black Sea. In 1831, a commercial port was established here, which, however, has not fulfilled the expectations that were formed regarding it, having surrendered its pre-eminence to Potti, a town about 70 miles to the south-east.

SOUL, in the language of spiritualistic philosophers, covers the whole region of mind, and is generally conceived of as a naturally imperishable entity, in relation with the body, but definable, for the most part, only in terms of the complete negation of material attributes. With this the popular conception in the main coincides, though it is less laboured, and considerably less negative. In its original signification, the word appears to have stood for the principle of life both in men and in animals. The modes of conceiving it were various: it was sometimes regarded as the mere harmony of the bodily functions, and sometimes as a distinct entity of highly ethereal nature, and generally supposed to be seated in, or connected with, the blood; but no essential distinction was made between the soul of man and the soul of brutes. Very soon, however, the manifest superiority of man to the lower creation suggested difficulties, which were increased as the thought of an after-life, in a different sense from transmigration, was gradually developed. And in man, the constant war among his members, the opposition of passion and reason, as it began to be observed with the growing habit of introspection, called for some explanation which should apply to humanity only. To meet all such difficulties, a 'Trichotomy,' or three-fold division of the human constitution, was assumed, according to which a naturally immortal and rational element was supposed to make part of man, besides the animal soul (always variously conceived) which he shared with the brutes. Between the two distinct elements—the animal and the rational soul—the various mental energies were differently apportioned by different thinkers, according as those energies were thought more or less noble and divine. Without going back upon obscure traditions regarding the beliefs of the early peoples, Plato's views may be cited as amounting to a Trichotomy, and in Aristotle there is the distinct mention of a noetic principle in man by the side of the animal soul. Later Greek schools put forward a similar view; and Philo, the forerunner of the Neo-Platonists, even spoke of *the soul of the soul*. Lucretius has the same curious expression, to which corresponds the distinction of Roman writers in general between *animus* and the animal soul, *anima*. The earliest Christian writings occasionally distinguish body, soul, and spirit (*pneuma*). Such a threefold division was unfamiliar to the Jewish mind, which appears to have rested in a kind of dualism, and was removed even from the common Greek philosophical expression, *pneuma* being the word employed by Stoic dualists to describe the fine ethereal nature of the material soul. It is hard to say whether a thorough-going Trichotomy was meant by the Christian writers, or whether the soul was not merged in either of the extreme elements—the coarse material body, or (as commonly conceived) the finely attenuated but still material spirit. Till about the 4th c., the language of Trichotomy prevailed in the Christian writings, but thenceforth the doctrine became suspect, having been specially appropriated by certain heretical sects, and soul and spirit came to be identified in substance, and distinguished only in function. Aquinas, and, later, Calvin, pronounced in favour of the dualistic rendering, after which modern popular expression has been moulded, chiefly through the predominant influence of spiritualism since the time of Descartes. This gives prominence to the word soul over spirit, except in religious and purely metaphysical aspects. The successors of Descartes have followed him in calling the single soul at once both rational and sensitive; but in rejecting, almost without exception, his description of the lower animals as mere mechanical automata, they have ignored, without an attempt to explain, the real difficulty that he sought to get rid of, and that the Trichotomy sought to meet. The ancient doctrine has been revived in various shapes by Paracelsus, Van Helmont, the anatomist Willis, De Maistre, and others.

The Egyptian doctrine of the soul is one of the most important, as it is the most ancient, for this nation appears to have been the first to declare that the soul was immortal. The genesis of the soul itself, however, is not defined by the monuments, although the existence of a cosmic soul, from which the others proceeded, is mentioned by ancient authors. The following may be gathered from a comparison of the papyri and monuments with the traditions handed down by the classical writers:—The soul itself, once separated from the cosmic or mundane soul, was supposed to undergo numerous transmigrations, passing from one animated body to another till its cycle of existence was fulfilled. The soul was considered to be essentially distinct from the body, and only connected with it through the link of life. It was represented in the hieroglyphs by several signs, as a basket of fire, a heron, a hawk with a human face, and a ram. Its nature was divine, but after death it passed to the great judgment in the hall of the Two Truths, where it was tried before Osiris and the forty-two assessors or demons of the dead, whose verdict determined its future destiny. This

depended upon the sins it had perpetrated during life, and which more or less interfered with its transmigration through the necessary cycle of existence till its ultimate union with the deity, and reception into the Egyptian heaven. In the judgment, it was accused by the enemy or accuser; and after the judgment, it was either devoured or annihilated, passed to the region of the Egyptian hell, or to the place of the metempsychosis, from which it entered some body of man or animal on the point of entering into existence. The great desire of the dying, indeed, was, that his soul should pass off the earth, its detention here preventing its ascent to the moon or heaven. The souls of the wicked passed into the Egyptian Hades, which the sun was supposed to traverse during the hours of the night. There they were subjected to punishments of a corporeal rather than spiritual nature—burned in brasiers, plunged into streams, kept in utter darkness, and deprived of the presence of the Sun-god, uttering fearful howls and wails in the prisons within which they were confined. After the passing of the great judgment, the soul underwent a series of transformations and adventures in the future state. It was justified, as Osiris had been, against the accusations laid to its charge by evil spirits. It assumed the form of a hawk, heron, swallow, and of a snake with a human head —that of the cosmic soul. In the fields of the Aah-en-ru, or Ahlu, the Egyptian Elysium, it sowed and reaped the harvest of gigantic grain which grew in that happy plain. It ascended the *makhen*, or mystical bark, and rowed through the winding of the celestial Nile, passed the fiery caldron of the Hades, revisited the body, entered the boat of the Sun, and passed through different regions of the Egyptian hell, in which the damned were detained, arriving at last at the manifestation to light. To preserve the body, in order that the soul might revisit and probably reanimate it at a future period, not only was it embalmed with the greatest care, but amulets were attached to it which were supposed to have the power of retaining the vital warmth, and of protecting it from destruction or decay. The period after which the soul was supposed to enter again into a human body was 3000 years, during which it transmigrated through other orders of animated nature. The principal dogmas, indeed, of the soul amongst these people were its creation or emanation from the cosmic soul, its transmigrations, and its final reception into heaven, where it lived in the boat of the Sun, and traversed the liquid ether in company with that luminary. The Pythagorean and Platonic schools seem to have drawn extensively from Egyptian sources in regard to the nature and destiny of the soul. The Brahmanical and Buddhistic notions of the soul have also much in common with the Egyptian. See BUDDHISM, TRANSMIGRATION.—Herodot. ii. 23; Plutarch, *De Isid.* c. 29; Hermes, *Clavis;* Prichard, *Egypt. Mythol.;* Rheinisch, *Denkm. in Miramar* (Wien, 1865).

SOULOUQUE. See FAUSTINUS I.

SOULS, CURE OF (Lat. *cura animarum*, care of souls), the technical phrase by which the canon law describes the charge which is given to a pastor, no matter of what degree of dignity, over the spiritual concerns of a flock; and the words especially imply the right of administering the sacraments. In this sense, the phrase is used to mark an important distinction between two classes of benefices or church livings—'benefices with,' and 'benefices without,' the cure of souls. Of the latter class are canonries, prebends, and the whole class known in the canon law as 'simple benefices.' Of the former are parochial cures, vicarial cures, and still more the higher charges of archbishop, bishop, &c.

SOULT, NICOLAS-JEAN DE DIEU, Duke of Dalmatia, and Marshal of France, the son of a notary, was born at Saint-Amens-la-Bastide, in the dep. of Tarn, March 29, 1769. In 1785, he enrolled himself as a private in the Royal Infantry regiment; and so distinguished himself by his steady obedience to discipline, indomitable *sang-froid*, and general intelligence, that in 1792 he became adjutant-major. His behaviour at Fleurus gained for him (October 11, 1794) the brevet of general of brigade. From 1794 to 1799, he was employed on the eastern frontier, and in the retreat after the defeat of Stockach (March 25, 1799), his able handling of the rear-guard alone prevented the annihilation of the French army. Appointed general of division (April 21, 1799), and put under Massena, whom he ably seconded in Switzerland and Italy, he was afterwards, on the warm recommendation of Massena, appointed by Napoleon to one of the four colonelships of the consular guards, and now became an ardent Napoleonist. This devotion, doubtless, was a great means of his obtaining the bâton of Marshal of France; but he most certainly justified his appointment by his brilliant achievements in the subsequent campaign against the Austrians, closed by the battle of Austerlitz, which he decided by piercing the Russian centre. He also did good service in the Prussian campaign; and took an important, though not a prominent part, in the Russian campaign of 1806—1807, after which he was appointed governor of Berlin, and created Duke of Dalmatia. S. was next placed at the head of the second corps in Spain, pursued the retreating British, attacked them at Coruña, and though repulsed, forced them to leave all their matériel behind. He then conquered Portugal, and exercised vice-regal authority over it, but the sudden arrival of Wellesley at Coimbra, and of Beresford at Chaves, made him retreat rapidly to Galicia. In September 1809, he became commander-in-chief in Spain, gained a brilliant victory at Ocana (18th November); and at the commencement of the following year, overran and subdued Andalusia, continuing to command in person the southern army. In attempting to succour Badajos, which he had captured and garrisoned (March 11), he was defeated by Beresford at Albuera (May 16, 1811). After the battle of Salamanca, and the advance of the British on Madrid, S. became thoroughly disgusted at the rejection of his admirable plans for transferring the theatre of war to Andalusia, and demanded and obtained his recall; but on the news of Vittoria (q. v.) reaching Napoleon, S., whom alone he considered capable of turning the tide of ill-fortune, was, in all haste, restored to the command-in-chief of the army of Spain. Now, however, it was not in Spain but in France that the contest had to be waged, and the advantages of numbers, discipline, and prestige were all on the enemy's side; nevertheless, by a system of military tactics which has been universally admired, he completely neutralised the consummate strategy of Wellington, and reduced the campaign, during the seven months it lasted, to a mere trial of strength, the defeats which he sustained at Orthez and Toulouse being due to the superiority of the British soldiers, not of their general. With his usual suppleness of character, he became an ardent royalist after the abdication of Napoleon; but on the return of the latter from Elba, he abandoned Louis XVIII., and became major-general of the imperial army. After Waterloo, he rallied the army at Laon; and on July 3d, at the council of war, coincided with Carnot as to the

uselessness of further resistance. To avoid the punishment due to his treachery, he published a memoir traducing Napoleon in the basest manner, and lauding the 'lawful princes' (i. e., the Bourbons); but in spite of this he was banished, and not recalled till May 1819; however, in the course of a few years more, he was restored to all his former honours, and took an active part in politics, and in the development of French industry. In 1838, he was sent as ambassador to England, and, as the great antagonist of Wellington, was received with the utmost enthusiasm. In 1845, he retired from active duty, was honoured with the appointment of 'Marshal-general of France,' and retired to his residence at Soultberg, where he died, November 26, 1851. In the following year, a statue of him, in white marble, was placed in the galleries of Versailles. See S.'s *Mémoires;* also, Napier's *History of the Peninsular War;* Thiers's *Histoire de la Revolution et de l'Empire;* and Salle's *Vie Politique du Maréchal S.* (1834).

SOUND (Lat. *sonitus*) is the impression produced on the Ear (q. v.) by the vibrations of the elastic medium, such as air or water, in which it is plunged. That this is the case, is proved, *first*, by the fact, that a bell or tuning-fork *in vacuo* gives no sound when struck; *second*, by the fact, that mere currents, as such (winds, running water, &c.), do not produce the sensation of sound until they are frittered down into vibratory motions by obstacles.

The most untutored ear distinguishes at once between a mere *noise* and a *musical note*. It of course distinguishes a *loud* sound from a faint one. Moreover, it distinguishes musical notes from one another by their shrillness or gravity, or, as it is technically called, their *Pitch*. Again, as in the case of vowel-sounds sung to the *same* musical note, or as in the case of different instruments (flute and violin, for instance) playing the same note, it distinguishes something further—which is called the *Quality* of the note. It is on the pitch of notes that the Theory of Music (q. v.) is based, for the quality is only of importance in giving variety, as in orchestral music—or in giving richness of tone in a solo. The most perfect *music*, so far as theory goes, may be executed on the poorest instrument, but it gives little pleasure from the want of richness or quality. In the same way, a singer may possess faultless intonation, yet the performance, though *musically* perfect, may, from the harsh quality of the voice, be unpleasant. We intend, in the present article, to avoid everything connected with music, and have made these remarks to shew that there is something in the theory of sound more profound than is contemplated in the theory of music.

The questions we have now to discuss are:

1. What constitutes the difference between a mere noise and a musical note?
2. On what does the pitch of a note depend?
3. On what does its quality depend?

The answers to these queries are all contained in the following statement:

Every musical note consists in the repetition, at equal small intervals of time, of some definite noise; the pitch depends on the rate of repetition; and the quality upon the nature of the fundamental noise.

Rough experimental illustrations of the parts of this statement are easily given, more refined ones will be afterwards alluded to. If, for instance, the edge of a card be held to a revolving toothed-wheel, a definite noise is produced as each tooth bends the card and allows it to spring back. While the wheel revolves slowly, we can distinguish these successive noises; but when it is revolving so fast that they are no longer separately distinguishable, the character of the sound changes completely. It now becomes continuous, and, so far as the ear can detect, uniform, and thus becomes a musical note (with such an apparatus, not a pleasing one). As the wheel is made to revolve faster and faster, the pitch of the note rises, till it becomes a sort of shriek, and finally becomes inaudible. The *Sirène* (q. v.) gives another excellent illustration. In this case, the fundamental noise is produced by a puff of air escaping from an orifice; and we observe, just as before, that the greater the number of such puffs per second, after they have become so frequent as to be separately undistinguishable, the higher is the pitch of the musical note produced.

Now, if by machinery we arrange matters so that the sirène and the toothed-wheel give the number of puffs and the number of impacts on the card the same per second, the musical note produced by each has the same pitch. But the notes differ greatly in quality, the one being exceedingly soft and pleasant, the other harsh and grating. The pitch, therefore, depends on the number of noises per second, and the quality upon the nature of the fundamental noise. We shall find a complete theoretical proof of this later.

The general nature of the mechanical process by which sound is propagated in the air will be illustrated, and compared with other cases of wave-motion, in our article on WAVES. Meanwhile, it is only necessary for us to observe that, as the velocity of sound is ten times greater than that of wind in the most violent hurricane, it is not *air* itself which is transferred from place to place, but a *state of disturbance* (condensation or rarefaction) of the air. Each successive layer of air in the path of the sound suffers this disturbance in turn, and by virtue of its Elasticity (q. v.), passes it on to the next.

Newton was the first who attempted to deduce from mechanical principles the velocity of sound, but only for the particular case in which each particle of air, in the path of the sound, is supposed to move backwards and forwards according to the same law as the bob of a Pendulum (q. v). He shewed that this species of motion is consistent with the elastic properties of air, as given by Boyle's or Mariotte's Law (q. v.), viz., that the pressure of air is proportional to its density. The velocity of sound in this case is of course to be found from the time which elapses between the commencement of the motion of any one particle of air, and that of another at a given distance from it, in the direction in which the sound is moving. The numerical result deduced by Newton with the then received experimental data for the compressibility of air, was 979 feet per second. This investigation was very defective, applying, in fact, solely to the special case of a pure musical note, continually propagated without lateral divergence; yet the solution obtained by Lagrange from a complete analysis of the question, gave precisely the same mathematical result.

But, by direct measurements, carefully made, by observing at night the interval which elapses between the flash and the report of a cannon at a known distance, the velocity of sound has been found to be considerably greater—in fact, about 1090 feet per second, at the temperature of freezing water.

Newton seeks for the cause of this discrepancy between theory and observation in the idea that the size of the particles of air is finite compared with their mutual distance; and that sound is instantaneously propagated through the particles themselves. Thus, supposing the particles to have a diameter $\frac{1}{9}$th of the distance between them, we must add $\frac{1}{9}$th to the space travelled by sound in a second, i. e., to the velocity—which will thus be

brought up to $(1 + \frac{1}{9})$ 979 feet = 1088 feet nearly, which is a very close approximation to the actual value given above.

This is not one of Newton's happiest conjectures—for, independent of the fact that such an assumption would limit definitely the amount of compression which air could undergo, and, besides, is quite inconsistent with the truth of Boyle's law for even moderate pressures, it would result from it that sound should travel slower in rarefied, and quicker in condensed air. Now, experiment shews that the velocity of sound is unaffected by the height of the barometer; and, indeed, it is easy to see that this ought to be the case. For in condensed air the pressures are increased proportionally to the increase of condensation, and the mass of a given bulk of air is increased in the same proportion. Hence, in a sound-wave in condensed air, the forces and the masses are increased proportionally, and thus the rate of motion is unaltered. But the temperature of the air *has* an effect on sound, since we know that the elastic force is increased by heat, even when the density is not diminished; and therefore the velocity of sound increases with the temperature at the rate of about $4\frac{1}{2}$ feet per Fahrenheit degree, as is found by experiment.

Newton's explanation of the discrepancy between theory and experiment being thus set aside, various suggestions were made to account for it; some, among whom was Euler, imagining that the mathematical methods employed, being only approximate, involved a serious error.

The explanation was finally given by Laplace, and is simple and satisfactory. When air is *suddenly* compressed (as it is by the passage of a sound-wave), it is heated; when suddenly rarefied, it is cooled, and this effect is large enough to introduce a serious modification into the mathematical investigations. The effect is in either case to *increase* the forces at work—for, when compressed, and consequently heated, the pressure is greater than that due to the mere compression—and, when rarefied, and consequently cooled, the pressure is diminished by more than the amount due to the mere rarefaction. When this source of error is removed, the mathematical investigation gives a result as nearly agreeing with that of observation as is consistent with the unavoidable errors of all experimental data. It is to be observed that, in noticing this investigation, nothing has been said as to the pitch or quality of the sound, for these have nothing to do with the velocity. It must, however, be remarked here that, in the mathematical investigation, the compressions and rarefactions are assumed to be very small; i. e., the sound is supposed to be of moderate intensity. It does not follow, therefore, that very violent sounds have the same velocity as moderate ones, and many curious observations made during thunder-storms seem to shew that such violent sounds are propagated with a greatly increased velocity. (See a paper by Earnshaw in the *Phil. Mag.* for 1861.) It is recorded that in one of Parry's arctic voyages, during gun-practice, the officer's command 'Fire' was heard at great distances across the ice *after* the report of the gun.

Since sound consists in a wave-propagation, we should expect to find it exhibit all the ordinary phenomena of Waves (q. v.). Thus, for instance, it is *reflected* (see ECHO) according to the same law as light. It is *refracted* in passing from one medium to another of different density or elasticity. This has been proved by concentrating in a focus the feeble sound of the ticking of a watch, and rendering it audible at a considerable distance, by means of a lens of collodion films filled with carbonic acid gas.

Sounds *interfere* to reinforce each other, or to produce silence; just as the crest of one wave in water may be superposed on the crest of another, or may apparently destroy all motion by filling up its trough. The simplest mode of shewing this is to hold near the ear a vibrating tuning-fork and turn it slowly round its axis. In some positions, the sounds from the two branches reinforce, in others they weaken, each other. But if, while the sound is almost inaudible, an obstacle be interposed between the ear and one of the branches, the sound is heard distinctly. Beats, which will shortly be alluded to, form another excellent instance.

To give an idea of the diminution of loudness or intensity of a sound at a distance from its source, let us consider a series of spherical waves diverging from a point. The *length* of a wave, as we know from the theory, does not alter as it proceeds. (Indeed, as we shall presently see, the pitch of a note depends on the length of the wave; and we know that the pitch is not altered by distance.) Hence, if we consider any one spherical wave, it will increase in radius with the velocity of sound, but its thickness will remain unaltered. The same disturbance is thus constantly transferred to masses of air greater and greater in proportion to the *surface* of the spherical wave, and therefore the amount in a given bulk (say a cubic inch) of air will be inversely proportional to this surface. But the surfaces of Spheres (q. v.) are as the squares of their radii—hence the disturbance in a given mass of air, i. e., the loudness of the sound, is inversely as the square of the distance from the source. This follows at once from the law of conservation of energy (see FORCE), if we neglect the portion which is constantly being frittered down into heat by fluid friction. All sounds, even in the open air, much more rapidly in rooms, are extinguished ultimately by conversion into an equivalent of heat. Hence sounds really diminish in intensity at a greater rate than that of the inverse square of the distance; though there are cases on record in which sounds have been heard at distances of nearly 200 miles. But if, as in speaking-tubes and speaking-trumpets, sound be prevented from diverging in spherical waves, the intensity is diminished only by fluid friction, and thus the sound is audible at a much greater distance, but of course it is confined mainly to a particular direction.

As already remarked, the purest sounds are those given by a tuning-fork, which (by the laws of the vibration of elastic solids) vibrates according to the same law as a pendulum, and communicates exactly the same mode of vibration to the air. If two precisely similar tuning-forks be vibrating with equal energy beside each other, we may have either a sound of double the intensity, or anything less, to perfect silence, according to their relative *phases*. If the branches of both be at their greatest elongations simultaneously, we have a doubled intensity—if one be at its widest, and the other at its narrowest, simultaneously, we have silence, for the condensation produced by one is exactly annihilated by the rarefaction produced by the other, and *vice versâ*. But if the branches of one be loaded with a little wax, so as to make its oscillations slightly slower, it will gradually fall behind the other in its motion, and we shall have in succession every grade of intensity from the double of either sound to silence. The effect will be a periodic swelling and dying away of the sound, and this period will be longer the more nearly the two forks vibrate in the same time. This phenomenon is called a *beat*, and we see at once from what precedes, that it affords an admirable criterion of a perfect *unison*, that is, of two notes whose pitch is the same. It is easy to see, b

the same kind of reasoning, that if two forks have their times of vibration nearly as 1 : 2, 2 : 3, &c.—i. e., any simple numerical ratio—there will be greater intervals between the beats according as the exact ratio is more nearly arrived at.

We must now consider, so far as can be done by elementary reasoning, the various simple modes of vibration of a stretched string, such as the cord of a violin. Holding one end of a rope in the hand, the other being fixed to a wall, it is easy (after a little practice) to throw it into any of the following forms,

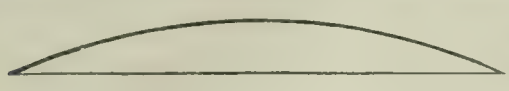


Fig. 1.

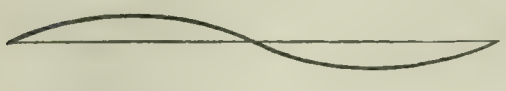

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

the whole preserving its shape, but rotating round the horizontal line. If the tension of the rope be the same in all these cases, it is easy to see that the times of rotation must be inversely as the number of equal segments into which the rope is divided; for the various parts will obviously have the same form; and the masses and distances from the axis of rotation being proportional to their lengths, the Centrifugal Forces (q. v.) will be as the squares of the lengths, and inversely as the squares of the times of rotation. But these centrifugal forces are balanced by the components of the tensions at the extremities, in directions perpendicular to the horizontal line; which are, by hypothesis, the same for all the figures. Hence the time of rotation is directly as the length of each segment. Now (see PENDULUM) any such rotation is equivalent to two mutually perpendicular and independent pendulum vibrations of the cord from side to side of the horizontal line. Thus, a violin-string may vibrate, according to the pendulum law, in one plane, either as a *whole* (fig. 1), as *two halves* (fig. 2), as *three thirds* (fig. 3), &c.; and the times of vibration are respectively as 1, $\frac{1}{2}$, $\frac{1}{3}$, ... Nay, more, any two or more of these may coexist in the same string, and thus, by different modes of bowing, we may obtain very different combinations of simple sounds: a *simple sound* being defined as that produced by a single pendulum motion, such as that of a tuning-fork, or one of the uncomplicated modes of vibration of a string.

The various simple sounds which can be obtained from a string are called *Harmonics* of the fundamental note; the latter being the sound given by the string when vibrating as a whole (fig. 1). For each vibration of the fundamental note, the harmonics have two, three, four, &c. Of these, the first is the octave of the fundamental note; the second the twelfth, or the fifth of the octave; the third the double octave; and so on. Thus, if we have a string whose fundamental note is C, the series of simple sounds it is capable of yielding is:

C, C_1, G_1, C_2, E_2, G_2 ($B\flat_2$), C_3, D_3, E_3, &c.

Of those written, all belong to the ordinary musical scale except the seventh, which is too flat to be used in music. This slight remark shews us at once how purely artificial is the theory of music, founded as it is, not upon a physical, but on a sensuous basis.

To produce any one of these harmonics with ease from a violin-string, we have only to touch it lightly at $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. of its length from either end and bow as usual. This process is often employed by musicians, and gives a very curious and pleasing effect with the violoncello or the double-bass. The effect of the finger is to reduce to rest the point of the string touched; and thus to make it a point of no vibration, or, as it is technically called, a *Node*.

In the case of a pianoforte wire, a blow is given near one end, producing a displacement which runs back and forward along the wire in the time in which the wire would vibrate as a whole. The successive impacts of this wave on the ends of the wire (which are screwed to the sounding-board), are the principal cause of the sound. But more of this case later.

The theory of other musical instruments is quite as simple. Thus, in a flute, or unstopped organ-pipe, the sound is produced by a current of air passing across an orifice at the closed end. This produces a wave which runs along the tube, is reflected at the open end, runs back, and partially intercepts the stream of air for an instant, and so on. Thus the stream of air is intercepted at regular intervals of time, and we have the same result as in the Sirène (q. v.). In this case, there is *one* node only, viz., at the middle of the pipe. If we blow more sharply, we create two nodes, each distant from an end by $\frac{1}{4}$ of the length of the tube. The interruptions are now twice as frequent, and we have the first harmonic of the fundamental note. And so on, the series of harmonics being the same as for a string. We may easily pass from this to the case of an organ-pipe closed at the upper end. For if, while the open pipe is sounding its fundamental note, a diaphragm be placed at the node, it will not interfere with the motion, *since the air is at rest at a node.* That is, the fundamental note of a closed pipe is the same as that of an open pipe of double the length. By examining the other cases in the same way, we find that the numbers of vibrations in the various notes of a closed pipe are in the proportions 1 : 3 : 5 : 7 : &c., the even harmonics being wholly absent.

There is another kind of organ-pipe, called a reed pipe, in which a stream of air sets a little spring in vibration so as to open and close, alternately, an opening in the pipe. If the spring naturally vibrates in the time corresponding to any harmonic of the pipe, that note comes out with singular distinctness from the combination—just as the sound of a tuning-fork is strongly reinforced by holding it over the mouth-hole of a flute which is fingered for the note of the fork. If the spring and the tube have no vibration in common, the noise produced is intolerably discordant. The Oboe, Bassoon, and Clarionet are mere modifications of the reed-pipe; and so are Horns in general, but in them the reed is supplied by the lip of the performer. Thus, a Cornet, a Trumpet, or a French Horn, gives precisely the same series of harmonics as an open pipe.

The statements just made as to the position of the nodes in a vibrating column of air are not strictly accurate, for the note is always found to be somewhat *lower* than that which is calculated from the length of the tube and the velocity of sound. Hopkins shewed experimentally that the distance between two nodes is always *greater* than twice the distance from the open end to the nearest node. The mathematical difficulties involved

in a complete investigation of the problem were first overcome by Helmholtz in 1859, in an admirable paper published in *Crelle's Journal*. The results are found to be in satisfactory accordance with those previously derived from experiment.

We have now to consider the subject of the quality of musical sounds; and one of its most important branches, what constitutes the distinction between the various vowel-sounds. It had long been recognised that the only possible cause of this distinction between sounds *musically identical* must lie in the nature of the fundamental noise, or, to express it differently, the nature of the periodic motion of each particle of air. But it appears that Helmholtz was the first to enter upon a complete examination of the point, both mathematically and experimentally, and the results he has arrived at form by no means the least remarkable of the contents of his excellent work, *Die Lehre von den Tonempfindungen*, recently published.

It was established by Fourier, that any periodic expression whatever may be resolved into the sum of a number of simple harmonic terms, whose periods are, respectively, that of the original expression, its half, its third part, &c. Hence any periodic motion of air (i. e., any musical sound) may be resolved into a series of simple pendulum vibrations (i. e., pure musical sounds, such as those of tuning-forks), the first vibrating once in the given period, the second twice, and so on. These notes are, as we have seen, the several harmonics of the lowest. Hence the quality of a musical sound depends upon the number and loudness of the harmonics by which it is accompanied.

Two experimental methods were employed by Helmholtz, one analytical, the other synthetical. In the first he made use of resonance-cavities fitted to the ear, and giving scarcely any indication of external sounds until one is produced which exactly corresponds in pitch with the note which the cavity itself would yield. With a series of such cavities, tuned to the several harmonics of some definite note, the note was examined when played on various instruments, and when sung to different vowel-sounds. It was thus ascertained which harmonics were in each case present, and to what extent, producing the particular quality of the sound analysed. The second method was founded on the fact, already noticed, that a tuning-fork gives an almost pure musical sound (i. e., free from harmonics). A series of tuning-forks, giving a note and its harmonics, were so arranged as to be kept constantly in vibration by an electro-magnetic apparatus. Opposite to each was fixed a resonance-cavity exactly tuned to it, and capable of being opened more or less at pleasure. When all the cavities were shut, the sound was scarcely audible; so that by opening them in various ways, any combination of harmonics might be made to accompany the fundamental note. These combinations were varied by trial, until the quality of the resultant sound was brought to represent as nearly as possible that of some vowel. The results of this second series of experiments coincided with those of the first. It appears from these investigations that the German U is the quality of a simple sound, though it is improved by adding faintly the two lowest harmonics; that O depends mainly on the presence of the third harmonic; and so on with the other sounds. It also appears, and it is well known by experience, that different vowel-sounds, to be sung with accuracy, require to be sung to different notes, the proper note being that for which the cavity of the mouth is adapted for the production of the accompanying harmonics which determine the quality of the particular vowel.

In strings and pipes, as we have seen, the higher notes are strictly harmonics of the fundamental note, and therefore the sounds of instruments which depend on these simple elements are peculiarly adapted for music. On the other hand, when, as in masses of metal, &c., the higher notes are not harmonics of the fundamental note, the mixed sound is always more or less jarring and discordant. Such is the case with bells, trumpets, cymbals, triangles, &c.; and, in fact, these sounds are commonly characterised as 'metallic.' To produce from such instruments a sound as pleasing as possible, they must be so struck that as few as possible of the higher notes are produced, and these as feebly as possible. Thus, for instance, to get the most pleasing sound from a pianoforte-wire, it should not be struck at the middle, as in such a case the first, third, fifth, &c. harmonics of the fundamental note will be wanting. If, however, it be struck at about $\frac{1}{7}$th of its length from one end, the harmonics produced will be mainly the first five; and these all belong to the chord of the fundamental note, so that the sound produced is rich and full. See SOUND, by J. Tyndale.
